SITE CHARACTERIZATION AND REMEDIAL ACTION CONCEPTS FOR THE WEST LAKE LANDFILL

Docket No. 4G-8801

Manuscript Completed: July 1989 Date Published: July 1989

Office of Nuclear Material Safety and Safeguards U.S. Nuclear Regulatory Commission Washington, DC 20555

Exhibit 14-E

PREFACE

This report has as its basis a characterization of the West Lake Landfill site and evaluation of some potential remedial measures performed primarily by S. K. Banerji, W. H. Miller, J. T. O'Connor and L. S. Uhazy of the University of Missouri-Columbia. The Nuclear Regulatory Commission received the first and second drafts, then titled "Engineering Evaluation of Options for Disposition of Radioactively Contaminated Residues Presently in the West Lake Landfill, St. Louis County, Missouri," in 1984; thus most of the information in this report dates from 1983-1984. However, some more recent data, principally water sampling results, have been added. Waste disposal and other industrial activities have continued on the 200 acre site, as have activities in the vicinity, resulting in changes in details of topography, roads, etc. To provide a more complete view of the radioactive material in the landfill, use has been made of figures from the report titled "Radiological Survey of the West Lake Landfill, St. Louis County, Missouri," NUREG/CR-2722, May 1982.

The remedial action concepts in this report are those proposed by the contractor. Judgments expressed in this report about these concepts are in general those of the contractor, and do not necessarily represent the views of the Nuclear Regulatory Commission. For example, the cost estimates for these concepts are based on radium-226 concentrations whereas the long-term issue is dependent upon the thorium-230 concentrations.

Although some of its information has not been updated since 1984, this report is being released so as to make its collected information available to interested parties.

ABSTRACT

The West Lake Landfill is near the city of St. Louis in Bridgeton, St. Louis County, Missouri. In addition to municipal refuse, industrial wastes and demolition debris, about 43,000 tons of soil contaminated with uranium and its radio-active decay products were placed there in 1973. After learning of the radioactive material in the landfill, the U.S. Nuclear Regulatory Commission (NRC) had a survey of the site's radioactivity performed and, in 1983, contracted, through Oak Ridge Associated Universities (ORAU), with the University of Missouri-Columbia (UMC) to characterize the environment of the site, conduct an engineering evaluation, and propose remedial measures. This report presents a description of the results of the UMC work, providing the environmental characteristics of the site, the extent and characteristics of the radioactive material there, some considerations with regard to potential disposal of the material, and some concepts for remedial measures.

SUMMARY

In 1973, approximately 7900 metric tons (mt) (8700 short tons) of radioactively contaminated barium sulfate (BaSO₄) residues were mixed with about 35,000 mt (39,000 t) of soil, and the entire volume was placed in the West Lake Landfill in St. Louis County, Missouri. This material resulted from decontamination efforts at the Cotter Corporation's Latty Avenue plant where the material had been stored. Disposal in the West Lake Landfill was not authorized by the Nuclear Regulatory Commission (NRC) and was contrary to the disposal location indicated in the NRC records. State officials were not notified of this disposal since the landfill was not regulated by the State at the time. Although the contamination does not present an immediate health hazard, authorities have been concerned about whether this material poses a long-term health hazard to workers and residents of the area and what, if any, remedial action is necessary.

In 1980-81, Radiation Management Corporation (RMC) of Chicago, Illinois, performed a detailed radiological survey of the West Lake Landfill under contract to the NRC (NUREG/CR-2722). This survey was performed to determine the extent of radiological contamination. Before this survey, little was known about the location or activity of radionuclide-bearing soils in the landfill.

*This survey showed that the radioactive contaminants are in two areas. The northern area (Area 2) covers about 13 acres. The radioactive debris forms a layer 2 to 15 feet thick, exposed in only a small area on the landfill surface and along the berm on the northwest face of the landfill. The southern area (Area 1) contains a relatively minor fraction of the debris covering approximately 3 acres with most of the contaminated soil buried with about 3 feet of clean soil and sanitary fill.

The RMC survey showed that the radioactivity is from the naturally occurring U-238 and U-235 series with Th-230 and Ra-226 as the radionuclides that dominate radiological impact. The survey data indicate that the average Ra-226 concentration in the radioactive wastes is about 90 pCi per gram; the average Th-230

concentration is estimated to be about 9000 pCi per gram. Since Ra-226 has been depleted with respect to its parent Th-230, Ra-226 activity will increase in time (for example, over the next 200 years, Ra-226 activity will increase ninefold over the present level). This increase in Ra-226 must be considered in evaluating the long-term hazard posed by this radioactive material.

In addition to RMC's radiological survey, soil and water samples were collected and analyzed by others, including Oak Ridge Associated Universities (ORAU), and the University of Missouri-Columbia (UMC). Occasionally a sample of water from a monitoring well exceeds slightly the EPA drinking water standard of 15 pCi gross alpha per liter. Sample analyses for priority pollutants (non-radioactive hazardous substances) show a number of listed pollutants are present.

On the basis of radiological surveillance conducted by RMC, UMC, and ORAU, the following areas of concern have been identified:

- (1) Radioactive soil is eroding from the northwestern face of the berm, and is being transported off site.
- (2) Radon gas had been observed to accumulate to an unacceptable level in the Butler-type building on site. This building has since been removed.
- (3) Some degree of radiological contamination has been found in the wells that monitor the perimeter.
- (4) Surface exposure rates over much of the contaminated areas are greater than 20 $\mu R/hr$.

In March 1983, the NRC through ORAU, contracted with UMC to conduct an engineering evaluation of the site and propose possible remedial measures for NRC's consideration for dealing with the radioactive waste at the West Lake Landfill. The following six remedial options were proposed and evaluated in this study.

- o Option A No remedial action
- Option B Stabilization onsite with restricted land use

- o Option C Extending the landfill offsite with restricted land use
- o Option D Removal and relocation of the contaminated material to an authorized disposal site
- o Option E Excavation and temporary onsite storage in a trench
- Option F Construction of a slurry wall to prevent leachate from migrating off site

It is noted that some of the above alternatives for remedial action were initially evaluated with the objective of permanent disposal of the waste at the site.

1 INTRODUCTION

The West Lake Landfill is located in St. Louis County, Missouri, 6 km (3.7 miles) west of Lambert Field International Airport (Figure 1.1) and southwest of St. Charles Rock Road in Bridgeton, Missouri. The site has been used since 1962 for disposing of municipal refuse, industrial solid and liquid wastes, and construction demolition debris. In addition, the landfill is an active industrial complex on which concrete ingredients are measured and combined before mixing ("batching"), and asphalt aggregate is prepared. Limestone ceased to be quarried in the spring of 1987.

In 1973, 7900 metric tons [(mt) (8700 short tons)] of radioactively contaminated barium sulfate (BaSO₄) residues from uranium and radium processing were mixed with an estimated 35,000 mt (39,000 tons) of soil and deposited in the West Lake Landfill. Previously, this material was located at the Cotter Corporation's Latty Avenue facility in Hazelwood, Missouri, and was removed during decontamination work. It is not known what levels of contamination were already in the soil before the barium sulfate residues were mixed into it. Disposal in the West Lake Landfill was unauthorized and contrary to the disposal location indicated in the U.S. Nuclear Regulatory Commission's (NRC's) records.

Subsequently, the NRC sponsored studies that were directed at determining the radiological status of the landfill. In 1978, an aerial radiological survey revealed two areas within the landfill where the gamma radiation levels indicated radioactive material had been deposited. A more extensive survey was initiated in November 1980 by the Radiation Management Corporation (RMC) under contract to the NRC.

In March 1983, the NRC through Oak Ridge Associated Universities (ORAU) contracted with the University of Missouri-Columbia Department of Civil Engineering to describe the environmental characteristics of the site, conduct an engineering evaluation, and propose possible remedial measures for dealing with the radioactive waste at the West Lake Landfill. In May 1986, ORAU sampled water from

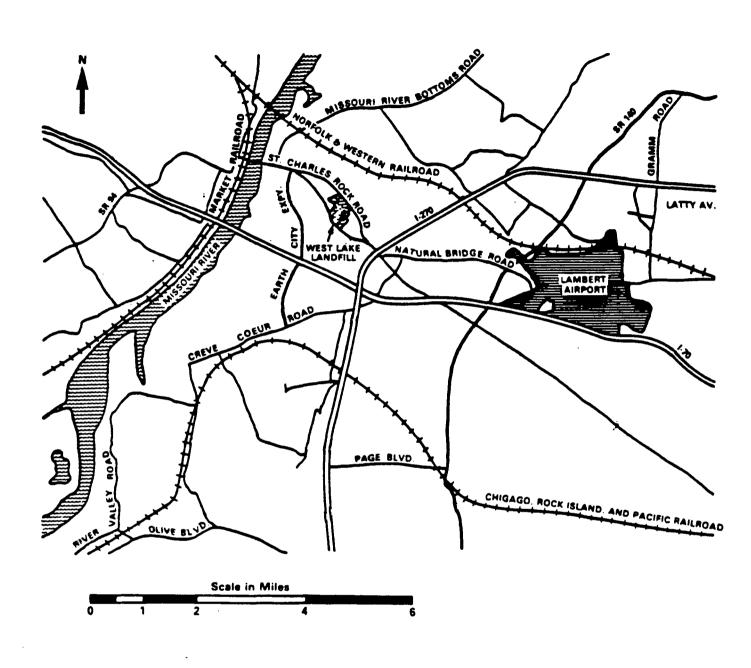

Figure 1:1 Location of West Lake Landfill

wells on and close to the landfill to determine if the radioactive material had migrated into the groundwater.

Information from all these sources forms the basis for this report.

2 SITE DESCRIPTION

This chapter presents a historical and environmental description of the West Lake Landfill site located in St. Louis County, Missouri.

2.1 Location

The 81-hectare (ha) (200-acre) West Lake Landfill property is situated between the St. Charles Rock Road and the Old St. Charles Rock Road in Bridgeton, Missouri. The southeastern and northwestern parts of the landfill abut farmland. Several commercial and industrial facilities are located near the landfill (Figure 2.1). The nearest residential area is a trailer park located approximately 1 km (0.6 mile) to the southeast. A major portion of the landfill (roughly the northern three-fourths of the site) is located on the floodplain, approximately 2 km (1.2 miles) from the Missouri River.

2.2 Zoning

The zoning plan obtained from the Bridgeton Planning and Zoning Department for properties on and adjacent to the landfill is shown in Figure 2.2. A portion of the landfill, including site Area 1, is zoned M-1, which is designated for light manufacturing; the northwest part of the landfill, including Area 2, is zoned as single-family residential (R-1). This R-1 zoning indicates the use to which the land was originally intended. However, the landfill was extended over the land zoned R-1, and the zoning plan was simply not changed to reflect the new usage. Other discrepancies between land use and zoning are found in the nearby Earth City Industrial Park (William Canney, Safety Supervisor of West Lake Landfill, Inc., personal communication, March 1984). The land across St. Charles Rock Road is zoned for light and heavy manufacturing. The remainder of the property surrounding the landfill is zoned residential and business.

2.3 History

The West Lake Landfill was started in 1962 for the disposal of municipal and industrial solid wastes, and to fill in the excavated pits from the quarry operations that had been performed at the site since 1939 (Canney, personal communication, March 1984). In 1974, the landfill was closed by the Missouri Department of Natural Resources (MDNR) (Karch, 1976). A new sanitary landfill, in an area of the West Lake Landfill property which is protected from groundwater contact, now operates under an MDNR permit.

This new part of the landfill was opened in 1974. The bottom is lined with clay and a leachate collection system has been installed. Leachate is pumped to a treatment system consisting of a lime precipitation unit followed in series by an aerated lagoon and two unaerated lagoons. The final lagoon effluent is discharged into St. Louis Metropolitan Sewer District sewers.

The quarrying operation ceased in the spring of 1987 because not enough "good rock" was left at the site.

2.4 Ownership

The West Lake Landfill was owned from 1939 until 1988 by West Lake Landfill, Inc., of 13570 St. Charles Rock Road, Bridgeton, Missouri. Most of the landfill was sold in 1988 to Laidlaw Industries, Inc. The two areas which contain the radioactive material were retained by West Lake Properties as the principal properties of a subsidiary named Rock Road Industries, Inc.

2.5 Contaminated Areas

Radioactive contamination at the West Lake Landfill has been identified in two separate soil bodies (Figure 2.3). Comparisons of radionuclide quantities and of the activity ratios between radionuclides not in secular equilibrium, indicate that the radioactive contamination in the separate soil bodies was derived from the same source, i.e., the Cotter Corporation's former Latty Avenue facility in Hazelwood, Missouri (NRC, NUREG/CR-2722).

The northern area (referred to as Area 2) of contamination shown on Figure 2.3 covers an area of 5.2 ha (13 acres) and lies above 5 to 6 m (16-20 ft) of landfill debris. The contaminated soil forms a more or less continuous layer from 1 to 4 m (3 to 13 ft) in thickness, and amounts to approximately 100,000 m³ (130,000 yd³). Some of this contaminated soil is near or at the surface, particularly along the face of the northwestern berm. Beneath the landfill debris, the soil profile consists of 1 to 2 m (3 to 7 ft) of floodplain top soil overlying 10 to 15 m (33 to 50 ft) of sand and gravel alluvium.

The southern area of contamination (referred to as Area 1) shown on Figure 2.3 covers approximately 1.1 ha (3 acres) and contains roughly 15,000 m³ (20,000 yd³) of contaminated soil. This body of soil is located east of the landfill's main office at a depth of about 1 m (3 to 5 ft), and is located over a former quarry pit, which was filled in with debris. The depth of debris beneath the contaminated soil is unknown, but is estimated to be 15 to 20 m (50 to 65 ft). Limestone bedrock underlies the landfill debris.

2.6 Topography

About 75% of the landfill site is located on the floodplain of the Missouri River. The site topography is subject to change because of the types of activities (e.g., landfilling and quarrying) performed there. Figure 2.3 shows a contour map of the site as of July 1986. The surface runoff follows several surface drains and ditches which run in a northwest direction and drain into the Missouri River.

1

2.7 Geology

2.7.1 Bedrock

Bedrock beneath the West Lake Landfill consists of Mississippian age limestone of the Meramacean Series of the St. Louis and Salem formations, which extends downward to an elevation of 58 m (190 ft) mean sea level (msl) (Figure 2.4).*

^{*}Missouri Department of Natural Resources, Division of Geology and Land Survey, Rolla, Missouri, Well Log Files.

The limestone is dense, bedded, and fairly pure except for intermittent layers which consist of abundant chert nodules. The Warsaw Formation—also of Mississippian age—lies directly beneath the limestone. The Warsaw is made up of approximately 12 m (38 ft) of slightly calcareous, dense shale; this grades into shaley limestone toward the middle of the formation (Figure 2.4) (Spreng, 1961). Bedrock beneath the site dips at an angle of 0.5° to the northeast. Eight kilometers (5 miles) east of the site, the attitude of the bedrock is reversed by the Florissant Dome; the bedrock dips radially outward from the apex of this dome at a low angle (Martin, 1966).

Since karst (solution) activity often occurs in carbonate rocks, the possibility of its occurrence in the West Lake Landfill area was considered. Brief observation of the quarry walls at the landfill suggests that some solution of the limestone has occurred, but this solution activity has apparently been limited (see Section 2.8.1) to minor widening of joints and bedding planes near the bedrock surface. Although karst activity within the limestone is relatively minor, the upper surface of the bedrock is irregular and pitted as a result of solution (Lutzen and Rockaway, 1971). This alteration of the bedrock surface is greatest beneath the Missouri River floodplain.

2.7.2 Soils

Soil material in this area may be divided into two categories: Missouri River alluvium and upland loessal soil. This demarcation is shown as the historical edge of the alluvial valley in Figure 2.5. The division is made on the basis of soil composition, depositional history, and physical properties. Because the West Lake Landfill lies over this transition zone, the surface material at the site varies considerably from southeast to northwest.

The Missouri River alluvium (Figure 2.6) ranges in thickness from 12 m (40 ft) beneath the landfill site to more than 30 m (100 ft) at mid-valley (Figure 2.7). The upper 3 m (10 ft) of the soil profile consists of organic silts and clays, that have been deposited by the Missouri River during floods.* Below this

^{*}Missouri Department of Natural Resources, Division of Geology and Land Survey, Rolla, Missouri, Well Log Files.

surface layer, the soil becomes sandy and grades to gravel at depths greater than 5 to 10 m (16 to 33 ft). Because of the effects of channel scour, which continues to grade the sediment after its initial deposition, the alluvium is fairly homogeneous in a horizontal direction and becomes progressively coarser with depth (Goodfield, 1965). At the edges of the floodplain, the alluvium is not as well graded, and a large amount of fine material is present in the deeper sand and gravel.

The upland loessal soil (Figure 2.8) is generally thinner than the floodplain soil, being usually less than 12 m (39 ft) thick, and was deposited during the age of Pleistocene glaciation. The loess consists of silt-sized particles that were transported by wind and deposited as a blanket over much of Missouri and Illinois. On the hills near the West Lake Landfill, the loess layer may be as much as 24 m (79 ft) thick. It consists of 6 to 9 m (20 to 30 ft) of fairly pure silt (Peoria loess) overlying 6 to 15 m (20 to 49 ft) of clay silt (Roxana loess) (Lutzen and Rockaway, 1971). This loess forms the hills to the southeast of the landfill, but it has long ago been removed from the landfill site and most of the surrounding valleys by erosion. The upper 1 m (3 ft) of the loess has been altered to form a thin soil profile. It should be noted that loess has a vertical permeability which is far greater than its horizontal permeability (Freeze and Cherry, 1979). The total permeability of loess is greatly increased by disturbance. The individual silt grains are generally quite angular, and therefore may not be effectively compacted by the methods commonly used to consolidate clay. The technique most effective in the compaction of loess would employ vibration beneath a surcharge. A relict soil profile from 5 to 10 m (16 to 33 ft) thick lies beneath the loess and directly on top of the bedrock. This soil was formed as a residuum before Pleistocene glaciation and was subsequently covered by the loess blanket. This soil is a highly consolidated clay containing abundant chert fragments (Lutzen and Rockaway, 1971). In addition to the natural geologic properties of the landfill, human disturbance of the soil must also be considered since material within the landfill itself can either limit or facilitate migration of leachate to the Missouri River alluvial aquifer.

In order to prevent downward movement of leachate, it is now a common practice to place a layer of compacted clay beneath sanitary landfills. Newer portions

of the landfill (constructed since 1974) have 2 to 3 m (7 to 10 ft) of clay at the base and around the sides. Waste is covered every day with 15 cm (6 in.) of compacted soil; the cover soil presently used is loess (of soil classifications CL and A4) taken from southeast of the landfill (Reitz and Jens, 1983a). If not properly compacted, this material may have a permeability of 0.0001 cm/sec (0.00004 in./sec) or more. It is not known what procedures for compaction, if any, were used at the landfill before 1974 since the site was unregulated in design as well as in materials which were accepted for disposal. It is believed, however, that there is no liner present beneath the northwestern portion of the landfill, and that sanitary (and, possibly, some hazardous) material was placed directly on the original ground surface. Since waste was periodically covered with soil to minimize rodent and odor problems, the landfill probably consists of discrete layers of waste separated by thin soil layers. Both areas containing radioactive material are in these presumably unlined above-ground portions of the landfill.

2.8 <u>Hydrology</u>

2.8.1 Subsurface Hydrology

Groundwater flow in the area surrounding the West Lake site is through two aquifers: the Missouri River alluvium and the shallow limestone bedrock. The base of the limestone aquifer is formed by the relatively impermeable Warsaw shale at an elevation of about 58 m (190 ft) msl (Figure 2.4). This shale layer has been reached, but not disturbed, by quarrying operations. Therefore, the Warsaw shale acts as an aquiclude, making contamination of the deeper limestone very unlikely. The Mississippian limestone beds have very low intergranular permeability in an undisturbed state (Miller, 1977). However, a strong leachate enters the quarry pit at an elevation of about 67 m (220 ft) msl (pt. A on Figure 2.5). This leachate is migrating vertically through more than 30 m (98 ft) of limestone. Explosive detonations associated with quarrying operations will tend to cause fractures to propagate in the quarry wall. These fractures have probably extended less than 10 m (33 ft) into the rock from the quarry face. Beyond this, the rock probably remains undisturbed. These fractures will tend to increase inflow to the quarry pit and allow leachate to percolate downward through the fractured zone. Thus, leachate inflow to the

quarry pit is not evidence of large-scale contamination of the limestone aquifer. The only other mechanism by which leachate could travel rapidly through the limestone is by transport through solution channels. Landfill consultants and quarry operators maintain that the limestone is fairly intact (Canney, personal communication, September 1983), and superficial observation of the quarry walls seems to support this conclusion. Since the limestone is fairly impervious, and groundwater flows in most areas from the bedrock into the alluvium, contamination of water in the bedrock aquifer does not appear likely.

The water table of the Missouri River floodplain is generally within 3 m (10 ft) of the ground surface, but at many points it is even shallower. At any one time, the water levels and flow directions are influenced by both the river stage and the amount of water entering the floodplain from adjacent upland areas. A high river stage tends to shift the groundwater gradient to the north, in a direction that more closely parallels the Missouri River. Local rainfall will shift the groundwater gradient to the west, toward the river and along the fall of the ground surface. This is inferred from water levels measured in monitoring wells at the West Lake site. The fact that groundwater levels commonly fluctuate more than does the Missouri River level, indicates that upland-derived recharge exerts a great deal of influence over groundwater flow at the West Lake site. This influence decreases toward the river.

The deep Missouri River alluvium acts as a single aquifer of very high permeability. This aquifer is relatively homogeneous in a downstream direction, and decreases in permeability near the valley walls. The deeper alluvium is covered by 2 to 4 m (7 to 13 ft) of organic silts and clays that may locally contain a large fraction of sand-sized particles. Water levels recorded between November 1983 and March 1984 in monitoring wells at West Lake* indicate a groundwater gradient of 0.005 flowing in a N 30°W direction beneath the northern portion of the landfill. This represents the likely direction of any possible leachate migration from the landfill (Figure 2.5).

^{*}Data supplied by Reitz and Jens engineering firm, St. Louis, 1984.

The alluvial aquifer recharges from upland areas from three sources: seepage from loess and bedrock bordering the valley, channel underflow of upland streams entering the valley, and seepage losses from streams as they cross the floodplain. Of these sources, streams and their underflow represent the main source of upland recharge to the alluvial aquifer. Streams entering the floodplain raise the water table in a fan-shaped pattern radiating outward from their point of entrance to the plain. In areas where streams are not present, the water slopes downward from the hills, steeply at first and then gently to the level of the free water surface in the Missouri River channel. The situations described above do not take into account the effect of variations in permeability of the shallow soil layer. Aerial photography of the site indicates that a filled backchannel (oxbow lake) type of soil deposit is present along the southwest boundary of the landfill (USDA, 1953). This deposit is probably composed of fine-grained material to the depth of the former channel (6 to 10 m) (20 to 33 ft). This deposit may tend to hamper communication between shallow groundwater on opposite sides of the deposit.

Since no other recharge sources exist above the level of the floodplain, the only water available to leach the landfill debris is that resulting from rainfall infiltrating the landfill surface. Because the underlying alluvial aquifer is highly permeable, there will be little "mounding" of water beneath the landfill. Because the northern portion of the landfill has a level surface it is likely that at least half of the rainfall infiltrates the surface. The remaining rainfall is lost to evapotranspiration and (to a lesser degree) surface runoff. Due to the height of the berm, temporary impoundment of surface runoff is a common occurrence.

No public water supplies are drawn from the alluvial aquifer near the West Lake Landfill. It is believed that only one private well (Figure 2.9) in the vicinity of the landfill is used as a drinking water supply. This well is 2.2 km (1.4 miles) N 35°W of the former Butler-type Building location on the West Lake Landfill. In 1981, analysis showed water in this well to be fairly hard (natural origins) but otherwise of good quality (Long, 1981).

Water in the Missouri River alluvium is hard and usually contains a high concentration of iron and manganese (Miller, 1977). The amount of dissolved

solids present in the water of the alluvial aquifer varies greatly; purity increases toward mid-valley where groundwater velocity is greatest. A water sample from a well in the alluvium 3 km (1.9 miles) north of the landfill had a total dissolved solids content of 510 mg/liter and total hardness as $CaCO_3$ of 415 mg/liter. Water in the limestone bedrock generally has a hardness greater than 180 mg/liter as $CaCO_3$ equivalent (Emmett and Jeffery, 1968). Total dissolved solids range from 311 to 970 mg/liter. Water in the limestone aquifer may contain a large amount of sulfate of natural origin (Miller, 1977).

2.8.2 Surface Hydrology

Because of the extremely low slope of the Missouri River flood plain surface, precipitation falling on the plain itself generally infiltrates the soil rather than running off the surface. The only streams present on the floodplain are those that originate in upland areas. Drainage patterns on the plain (Figure 2.9) have been radically altered by flood control measures taken to protect Earth City (Figure 2.1) and by drainage of swamps and marshes. Before these alterations, Creve Coeur Creek passed just south of the landfill, and drained a fairly large area. It has since been redirected to discharge into the Missouri River upstream (south) of St. Charles (Figure 2.9). The old channel still carries some water, and empties into the Missouri River 45.2 km (28 miles) upstream from the confluence with the Mississippi River. Near the landfill, this stream is usually dry. As it crosses the flood plain, the creek passes through shallow lakes which provide a more or less continuous flow to the Missouri River throughout the year. A second stream, Cowmire Creek, crosses the floodplain east of the site. This stream flows northward and joins a backwater portion of the Missouri River at kilometer 35.4 (22 miles). Because of the relationship which exists between river level and groundwater level in portions of the floodplain near the river, these streams may either lose flow (at low stage) or gain flow (at high stage).

The present channel of the Missouri River lies about 3 km (2 miles) west and northwest of the landfill. Early land surveys of this area indicate that 200 years ago the channel was located several hundred meters to the east (toward the landfill) of its present course (Reitz and Jens, 1983b). The Missouri River has a surface slope of about 0.00018 (Long, 1981). River stage at St. Charles

[kilometer 45.2 (mile 28)] is zero for a water level of 126.1 m (413.7 ft) msl (Reitz and Jens, 1983a). Average discharge of the Missouri River is 2190 m³/s (77,300 ft³/s), with a maximum flow of 2850 m³/s (101,000 ft³/s) for the period of April through July, and a minimum flow of 1140 m³/s (40,300 ft³/s) in January and December (Miller, 1977). Some average properties of Missouri River water for the period 1951-1970 were: alkalinity = 150 mg/liter as $CaCO_3$ equivalent; hardness = 209 mg/liter as $CaCO_3$ equivalent; pH = 8.1; and turbidity = 694 JTU (Jackson turbidity unit).

Water supplies are drawn from the Missouri River at kilometer 46.6 (mile 29) for the city of St. Charles, and the intake is located on the north bank of the river. Another intake at kilometer 33 (mile 20.5) is for the St. Louis Water Company's North County plant (Reitz and Jens, 1983a).

The city of St. Louis takes water from the Mississippi River, which joins the Missouri River downstream from the landfill. In this segment of the river, the two flow-streams have not completely mixed and the water derived from the Missouri River is still flowing as a stream along the west bank of the Mississippi River channel*. The intake structures for St. Louis are on the east bank of the river so that the water drawn is derived from the upper Mississippi.

2.9 Meteorology

The climate of the West Lake area is typical of the midwestern United States, in that there are four distinct seasons. Winters are generally not too severe and summers are hot with high humidity. First frosts usually occur in October; and freezing temperatures generally do not persist past March. Rainfall is greatest in the warmer months, (about one-quarter of the annual precipitation occurs in May and June) (Figure 2.10) (NRC, 1981). In July and August, thunderstorms are common, and are often accompanied by short periods of heavy rainfall. Average annual precipitation is 897 mm (35.3 in.), which includes the average annual snowfall of 437 mm (17.2 inches snow). Average relative humidity is 68%,

^{*}Ned Harvey, hydrologist with the USGS, telephone communication, August 1983.

and humidities over 80% are common during the summer. Wind during the period of December through April is generally from the northwest; winds blow mainly from the south throughout the remainder of the year. A compilation of hourly wind observations shows that although the wind resultant is fairly consistent on a monthly basis, the wind actually shifts a good deal and is very well distributed in all directions (Figure 2.11) (NRC, 1981; U.S. Department of Commerce, 1960).

Meteorological data used is from Lambert Field International Airport which is 6 km (3.7 miles) east of the West Lake site. Temperature and precipitation data are also representative of West Lake. However, because of differences in topography between Lambert Field and the site, the actual wind directions at West Lake may be slightly skewed in a NE-SW direction parallel to the Missouri River valley.

2.10 Ecology

The West Lake Landfill is biologically and ecologically diverse. Rather than a single ecological system (e.g., a prairie), it is a mosaic of small habitats associated with

- (1) moist bottomland and farmland adjacent to the perimeter berm
- (2) poor quality drier soils on the upper exterior and interior slopes of the berm
- (3) an irregular waste ground surface associated with the inactive portion of the landfill
- (4) aquatic ecosystems present in low spots on the waste ground surface

Generally, the natural systems which are present are limited by operations in the active portion of the landfill and form a corridor along the perimeter berm from near well site 75 (Figure 2.5), on the Old St. Charles Rock Road, clockwise to the main entrance to the landfill near well site 68, along St. Charles Rock

Road. The following observation and descriptions demonstrate the biological variety of these sites.

The flora of the perimeter berm extending from the southwest clockwise to the area of the main entrance to the landfill present a series of contrasts. Along the Old St. Charles Rock Road, the bottom and lower slope of the berm is heavily influenced by the nearby mature silver maple (Acer saccharinum), boxelder (Acer negundo), oak (Quercus), sycamore (Platanus), green ash (Fraximus pennsylvanica), and eastern cottonwood (Populus deltoides) trees associated with the old channel of Creve Coeur Creek. At the corner, between wells 59 and 60 (Figure 2.5), large silver maple and boxelder trees form a dense stand in the moist soils at the base of the berm. The density of these trees declines on this slope extending toward the north (well 61) and the Butler-type Building corner. The extension of this slope toward the northwest is dominated by a dense willow-like thicket in which a few eastern cottonwoods and a hawthorn tree have established. From this northwest corner of the landfill to the eastern limit of the trees between the landfill and St. Charles Rock Road (well 65), the exterior slope of the berm is dominated by dense stands of small and large eastern cottonwoods. This latter occurrence reflects the influence of the well-established eastern cottonwoods and sycamores associated with the permanent pond just north of this site (Figure 2.9). The ground cover along these exterior slopes consists of grasses, forbs, plants common to disturbed areas, seedling cottonwoods, and shrubs. A well-manicured grass groundcover continues from the limit of the trees to the area around the main entrance of the landfill and well 68. This vegetation contributes to the partial stabilization of the steep exterior slopes.

The somewhat drier top and the short, interior slope of the berm, colonized by prairie grasses such as bluestem (Andropogon), blends into the irregular surface of the inactive portion of the landfill. Depressions in this surface allow water to collect and tall grasses, foxtail, and plants characteristic of disturbed areas [e.g., ragweed (Ambrosia), mullein (Verbascum), pokeweed (Phytolacca), cinquefoil (Potentilla), sunflower (Helianthus), and plantain (Plantago)] are replaced by characteristic wetland species [e.g., algae (Spirogyra), cattails (Typha), sedges (Carex), and smartweed (Polygonium)]. Young eastern cottonwoods are established at several of these wet sites.

Generally, the surface vegetation of the inactive landfill gives way to barren waste ground around the Butler-type Building location and the barren terrain associated with recent landfill activities.

Animals were observed associated with these habitats. Cottontail rabbits (Sylvilagus) were encountered most frequently and their fecal pellets were observed on the landfill. Density of fecal material was particularly heavy in the thickets on the exterior slopes of the perimeter berm. In this regard, coyote (Canis latrans) feces containing rabbit fur were observed. Small mammals (rodents) were not seen but could certainly be present in these areas. Large ungulates also were not sighted, but tracks and feces of white-tailed deer indicate that they utilize the landfill.

The only birds observed were a crow (<u>Corvus</u>), several robins (<u>Turdus</u>), and white-crowned sparrows (<u>Zonotrichia leucophrys</u>). This certainly does not reflect the extent to which birds utilize these habitats, for observations were made early in the spring. It is readily apparent that returning migratory passerines would utilize the surface vegetation and berm thickets for nesting, cover, and feed later in the season. It is also possible that waterfowl could utilize the permanent ponds on the landfill and adjacent to St. Charles Rock Road. Twelve scaup (<u>Aythya</u>) and mallards (<u>Anas</u>) were observed on the lagoon which serves as part of the landfill waste water treatment facility.

Small puddles contained characteristic aquatic invertebrates and at least two species of amphibians. Casual examination of these shallow waters revealed three genera of snails (Physa, Lymnaea, Helisoma), an isopod (Asnellus), cyclopoid copepods, and cladocerans. Aquatic insect larvae were not observed; however, this does not rule out their presence. The sighting of a bullfrog tadpole (Rana catesbeiana) and audition of spring peepers (Hyla), indicates these ponds are utilized as breeding sites. No fish were observed in these puddles on the landfill surface; however, a dead gizzard shad (Dorsoma cepedianum) was seen in the pond adjacent to St. Charles Rock Road. The only reptiles seen were the water snake (Nerodia) and the garter snake (Thamnophis).

Although the northwest inactive portion of the landfill is posted with "No Trespassing" signs, it was evident that humans do encroach on these habitats.

Fishing tackle was found tangled in power lines and trees, and spent small-gauge shotgun shells were found on the landfill surface and berms.

2.11 Demographics

The West Lake Landfill is located in the northwestern portion of the city of Bridgeton, in St. Louis County, Missouri. Earth City Industrial Park is located on the floodplain 1.5 to 2 km (0.9 to 1.2 miles) northwest of the landfill. Population density on the floodplain is generally less than 10 persons per square kilometer (26 persons per square mile); and the daytime population (including factory workers) is much greater than the number of full-time residents.

Major highways in the area include Interstate 70 (I-70) and Interstate 270 (I-270), which meet south of the landfill at Natural Bridge Junction (Figure 1.1). The Earth City Expressway and St. Charles Rock Road lie, respectively, west and east of the landfill. The Norfolk and Western Railroad passes about 1 km (0.6 mile) from the northern portion of the landfill (Figure 1.1). Lambert Field International Airport is located 6 km (3.7 miles) east of the West Lake Landfill.

In addition to factories at Earth City, plants are operated by Ralston-Purina and Hussman Refrigeration across St. Charles Rock Road. The employees of these two plants probably comprise the largest group of individuals in close proximity to the contaminated areas for significant periods of time. The Ralston-Purina facilities are located 0.4 km (0.2 mile) northeast of the Butler-type Building location at the landfill. Considering that land in this area is relatively inexpensive and that much of it is zoned for manufacturing, industrial development on the floodplain will likely increase in the future.

Two small residential communities are present near the West Lake Landfill. Spanish Lake Village consists of about 90 homes and is located 1.5 km (0.9 mile) south of the landfill, and a small trailer court lies across St. Charles Rock Road, 1.5 km (0.9 mile) southeast of the site (Figure 2.1). Subdivisions are presently being developed 2 to 3 km (1.2 to 1.9 miles) east and southeast of the landfill in the hills above the floodplain. Ten or more houses lie east of the

landfill scattered along Taussig Road. The city of St. Charles is located north of the Missouri River at a distance greater than 3 km (1.9 miles) from the landfill.

Areas south of the West Lake Landfill are zoned residential; areas on the other sides are zoned for manufacturing and business (Figure 2.2). Most of the landfill is zoned for light manufacturing (M-1). However, approximately 0.3 km² (0.12 mi²) of the northern portion of the landfill is zoned for residential use; this includes the contaminated area around the Butler-type Building site. The field northwest of the landfill between Old St. Charles Rock Road and St. Charles Rock Road is under cultivation. Trends indicate that the population of this area will increase, but the land will probably be used primarily for industrial facilities.

Wind rose is for Lambert Field International Airport, Hazelwood, Missouri, and shows the percentage of hourly observations in each direction along with the average speed in that direction; for example: wind blew from the north 4.5% of the time at an average speed of 3.76 m/s.

Figure 2.11. Wind distribution for West Lake area

3 RADIOLOGICAL CHARACTERIZATION OF THE SITE

3.1 Radiological Surveillance

Approximately 43,000 mt (47,000 tons) of contaminated soil were reported to have been disposed of in the landfill. A fly-over radiological survey performed for the NRC in 1978 identified two areas of contamination at the West Lake Landfill.

Subsequently, from August 1980 through the summer of 1981, the Radiation Management Corporation (RMC), under contract to the NRC, performed an onsite evaluation of the West Lake Landfill (NRC, NUREG/CR-2722). The purpose of this survey was to clearly define the radiological conditions at the landfill. The results were to be utilized in performing an engineering evaluation to determine if remedial actions should and could be taken.

The area to be surveyed was divided into 10-m (33-ft) grid blocks and included the following measurements:

- (1) external gamma exposure rates 1 m (3.3 ft) above the surfaces and betagamma count rates 1 cm (0.4 in.) above surfaces
- (2) radionuclide concentrations in surface soils
- (3) radionuclide concentrations in subsurface deposits
- (4) gross activity and radionuclide concentrations in surface and subsurface water samples
- (5) radon flux emanating from surfaces
- (6) airborne radioactivity
- (7) gross activity in vegetation

3.2 Survey Results

External Gamma

Figure 3.1 shows the two areas of elevated external radiation levels as they existed in November 1980, at the time of the preliminary RMC site survey. As can be seen, both areas contained locations where levels exceeded 100 μ R/hr at 1 m (3.3 ft). In Area 2, gamma levels as high as 3000 to 4000 μ R/hr were detected. The total areas exceeding 20 μ R/hr were about 1.2 ha (3 acres) in Area 1 and 3.6 ha (9 acres) in Area 2.

External gamma levels measured in May and July of 1981 decreased significantly, especially in Area 1, because approximately 1.2 m (4 ft) of sanitary fill was added to the entire area and an equal amount of construction fill was added to most of Area 2. As a result, only a few hundred square meters (a few thousand square feet) in Area 1 exceed 20 μ R/hr. In Area 2, the total area exceeding 20 μ R/hr decreased by about 10%, and the highest levels were about 1600 μ R/hr, near the location of the Butler-type building.

Surface Soil Analyses

A total of 61 surface soil samples were gathered and analyzed on site for gamma activity. Samples were normally stored 10 to 14 days to allow ingrowth of radium daughters. Concentrations of U-238, Ra-226 (from Pb-214 and Bi-214), Ra-223, Pb-211, and Pb-212 were determined for each sample. Surface soil samples are located in Figures 3.2 and 3.3.

In all soil samples, only uranium and/or thorium decay chain nuclides and K-40 were detected. Offsite background samples were on the order of 2 pCi/g Ra-226. Onsite samples ranged from about 1 to 21,000 pCi/g Ra-226, and from less than 10 to 2100 pCi/g U-238. In those cases where elevated levels of Ra-226 were detected, the concentrations of U-238 were generally anywhere from a factor of 2 to 10 lower. In cases of elevated sample activity, daughter products of both U-238 and U-235 were found.

In general, surface activity was limited to Area 2, as indicated by surface beta-gamma measurements. Only two small regions in Area 1 showed contamination; both were near the access road across from the site offices.

In addition to onsite gamma analyses, 12 samples were submitted to RMC's radio-chemical laboratories for thorium and uranium radiochemical determinations. The results show all samples contain high levels of Th-230. The ratio of Th-230 to Ra-226 (Bi-214) is about 20 to 1.

Subsurface Soil Analysis

Subsurface contamination was assessed by extensively "logging" holes drilled through the landfill. Several holes were drilled in areas known to contain contamination, then additional holes were drilled at intervals in all directions until no further contamination was encountered. A total of 43 holes were drilled, 11 in Area 1 and, in Area 2, 32 including 2 nearby offsite wells for monitoring water. All holes were drilled with a 6-in. auger and lined with 4-in. PVC (polyvinyl chloride) casing. The location of these auger holes is shown in Figures 3.4 and 3.5.

Each hole was scanned with an NaI(T1) detector and rate meter system for an initial indication of the location of subsurface contamination. On the basis of the initial scans, 19 holes were selected for detailed gamma logging using the intrinsic germanium (IG) detector and multiple channel analyzer.

The results of the NaI(T1) counts and IG analyses show concentrations of Bi-214, as determined by the IG system, ranged from less than 1 to 19,000 pCi/g. For those holes where both NaI(T1) counts and IG counts were made, a good correlation between gross NaI(T1) counts and Ra-226 concentrations, as determined by in situ analysis of the daughter Bi-214 by the IG system, was found.

It was determined that the subsurface deposits extended beyond areas where surface radiation measurements exceeded 5 pCi/g. The approximate area of subsurface contamination compared to the area of elevated surface radiation levels shows a total difference in areas of 2 ha (5 acres).

The variations of contamination with depth for Areas 1 and 2 are shown in Figure 3.6. As can be seen, the surface elevations vary by about 6 m (20 ft), and the highest elevations occur at locations of fresh fill. Contamination (>5 pCi/g Ra-226) in several areas is found to extend from the surface to appreciable depths, about 6 m (20 ft) below the surface in two cases. In general, the subsurface contamination appears to be a continuous single layer, ranging from 0.6 to 4.6 m (2 to 15 ft) thick, located between elevations of 139 to 144 m (455 to 480 ft) and covering 6.5 ha (16 acres) total area.

In Figures 3.7 and 3.8, representations of the subsurface deposits are provided on the basis of auger hole measurements. These representations are consistent with the operating history of the site, which suggests that the contaminated material was moved onto the site and spread as cover over fill material. Thus, ** one would expect a fairly continuous, thin layer of contamination, as indicated by survey results.

Nonradiological Analysis

Six composite samples were submitted to RMC's Environmental Chemistry Laboratory for priority pollutant analysis. Five samples were taken from auger holes (one from Area 1 and four from Area 2) and the sixth from the West Lake leachate treatment plant sludge. The results indicate a significant presence of organic solvents in Area 2 samples. The results of the leachate sludge analysis were not as high as any of the soil samples.

A chemical analysis of radioactive material from both areas was also performed by RMC's laboratory. Results show elevated levels of barium and lead in most cases.

Background Radioactivity Measurement

Various offsite locations were selected for reference background measurements. The results of these measurements were within the normal range.

Airborne Radioactivity Analyses

Both gaseous and particulate airborne radioactivity were sampled and analyzed during this study. Since it was known that the buried material consisted partially or totally of uranium ore residues, the sampling program concentrated on measuring radon and its daughters in the air. Two methods were used: the first was a scintillation flask method for radon gas and the second was analysis of filter paper activity for particulate daughters.

A series of grab samples using the accumulator method were taken between May and August of 1981. A total of 111 samples from 32 locations was collected. Measurable radon flux levels ranged from 0.2 pCi/ m^2 s in low background areas to 865 pCi/ m^2 s in areas of surface contamination.

At three locations, repetitive measurements were made over a period of 2 months. These results are plotted in Figure 3.9. As can be seen, significant fluctuations were observed at two locations. The fact that these fluctuations were real and not measurement artifacts was later confirmed by duplicate charcoal canister samples, as described below.

A total of 35 charcoal canister samples was gathered at 19 locations over a 3-month period. The results show levels ranging from 0.3 pCi/ m^2 s to 613 pCi/ m^2 s. On 24 different occasions, the charcoal canisters and accumulator were placed in essentially the same locations, at the same time, for duplicate sampling. The results of this side-by-side study show generally good correlation between the two methods.

A set of 10-minute high-volume particulate air samples was taken to determine both short-lived radon daughter concentrations and long-lived gross alpha activity. The highest levels were detected in November 1980, near and inside the Butler-type building which has since been removed. These two samples approximately equal NRC's 10 CFR Part 20, Appendix B, alternate concentration limit of one-thirtieth WL for unrestricted areas.

In addition to the routine 10-minute samples, five 20-minute high-volume air samples were taken and counted immediately on the IG gamma spectroscopy system

to detect the presence of Rn-219 daughters. All samples were taken near surface contamination. In addition to Rn-222 daughter gamma activities, Rn-219 daughters were detected by measuring the low-abundance gamma rays of Pb-211. Concentrations of Rn-219 daughters ranged from 6×10^{-11} to 9×10^{-10} µCi/cc.

Vegetation Analysis

Vegetation samples included weed samples from onsite locations and farm crop samples (winter wheat) near the northwest boundary of the landfill. This location was chosen because runoff from the fill onto the farm field was possible. No elevated activities were found in these samples.

Water Analyses

A total of 37 water samples was taken: 4 in the fall of 1980, and the remainder in the spring and summer of 1981. One sample was equal to the U.S. Environmental Protection Agency (EPA) gross alpha activity standard for drinking water of 15 pCi/liter and that was a sample of standing water near the Butler-type building. Several samples, including all the leachate treatment plant samples, exceeded the EPA drinking water screening level for gross beta which would require isotopic analyses. Subsequent isotopic analyses indicated that the beta activity could be attributed to K-40. None of the offsite samples exceeded either EPA standard or screening level.

In 1981, MDNR collected 41 water samples which RMC analyzed for radioactivity (Table 3.1). Of these samples, 5 were background, 10 were onsite surface water, 10 were shallow groundwater standing in boreholes, and 16 were landfill leachate. From these data, background activity is estimated as 1.2 pCi/liter gross alpha and 27 pCi/liter gross beta. Results in Table 3.1 show the gross alpha in two water samples exceeded or equaled 15 pCi/l; the gross beta in ten water samples exceeded 50 pCi/l. Most of the gross beta activity comes from naturally occurring K-40 as determined from subsequent isotopic analysis.

In addition, groundwater samples in perimeter monitoring wells at the West Lake Landfill were taken by UMC personnel and ORAU in 1983, 1984, and 1986. The well locations are shown in Figure 2.5 and the results are presented in

Tables 3.2 and 3.3. Results in Table 3.2 show the gross alpha in two water samples slightly exceeded 15 pCi/l; the gross beta were all below 50 pCi/l in all water samples. Table 3.3 shows analyses were below 15 pCi/l for gross alpha and 50 pCi/l for gross beta for all the wells.

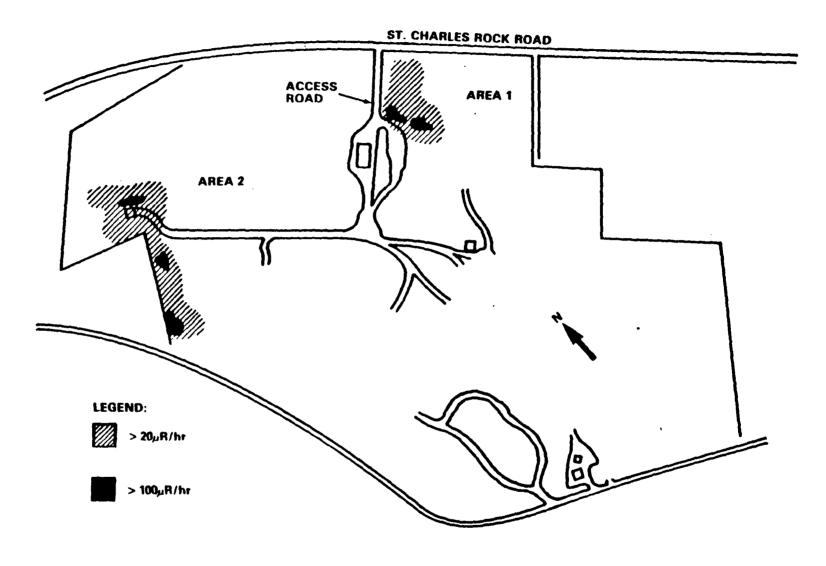

3.3 Estimation of Radioactivity Inventory

In examining the RMC report for bore hole samples (Table 3.3), it is noted that the naturally occurring U-238 to Th-230 to Ra-226 equilibrium has been disturbed. The RMC report (NRC, NUREG/CR-2722) indicates that the ratio of Ra-226 to U-238 is on the order of 2:1 to 10:1. This observation is consistent with the history of the radionuclide deposits in the West Lake Landfill, i.e., that they came from the processing of uranium ores to extract the uranium content and that the radioactive material at West Lake came from the former Cotter Corporation facility on Latty Avenue (presently occupied by Futura Coatings Company) in Hazelwood, Missouri. This location contains contamination from ore processing residues from which uranium had been previously separated, leaving the daughters behind at relatively higher concentrations. Additionally, it is noted in the RMC report that the ratio of Th-230 to Ra-226 is on the order of 5:1 to 50:1. This indicates that radium has also been removed. Other data are available in the Latty Avenue site study (Cole, 1981). Table 3.4 presents the radionuclide concentrations in Latty Avenue composite samples.

Using the RMC data and averaging the auger hole measurements over the two volumes of radioactive material found in Areas 1 and 2, a mean concentration of 90 pCi/g was calculated for Ra-226. Also, the ratios of Th-230 to Ra-226 were established since the level of Th-230 will determine the increase of Ra-226 with time. Although the ratio of Th-230 to Ra-226 ranged from 5:1 to 150:1, most of the data were in the 30:1 to 50:1 range. To ensure conservatism in estimating the long-term effects of Ra-226, a ratio of 100:1 was used for all further calculations.

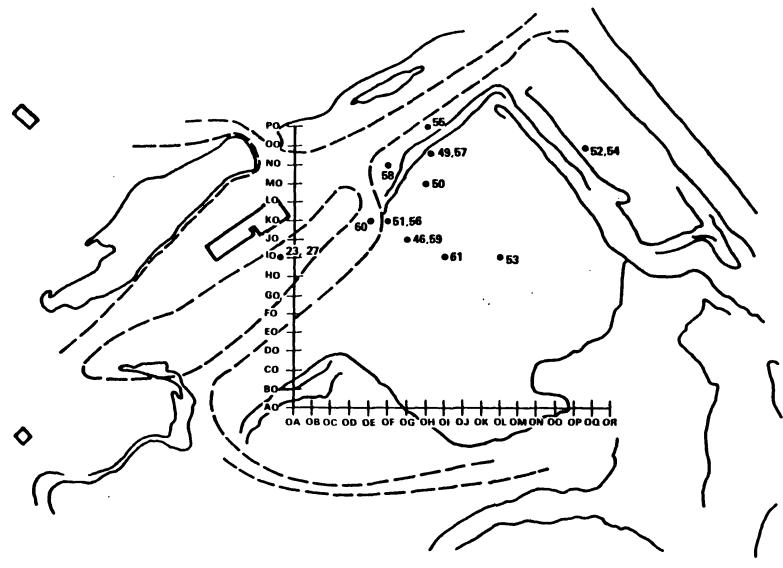

Using the Th-230:Ra-226 ratio of 100:1, the Th-230 activity is 9000 pCi per gram. If the U-238 concentration (as well as U-234 which would be similarly separated from the ore) is a factor of 5 less than Ra-226, this implies about 18 pCi U-238 per gram. The total mass of radioactive material (having Ra-226)

concentrations of 5 pCi/g or more) in the landfill was estimated by visually integrating the volume of radioactive material from graphs and multiplying by an average soil density, resulting in 1.5×10^{11} grams (150,000 metric tons) of contaminated soil. These numbers indicate that there are about 14 Ci of Ra-226 contained with its decay products in the radioactive material in the landfill. The material also contains about 3 Ci each of U-238 and U-234, and about 1400 Ci of Th-230. These estimates indicate the order of magnitude of the quantities to be dealt with, although the estimate for Th-230 is regarded as conservatively large.

4 APPLICABILITY OF THE BRANCH TECHNICAL POSITION

The NRC has established a Branch Technical Position (BTP) which identifies five acceptable options for disposal or onsite storage of wastes containing low levels of uranium and thorium (46 FR 52061, October 23, 1981). Options 1-4 provide methods under 10 CFR 20.302, for onsite disposal of slightly contaminated materials, e.g., soil, if the concentrations of radioactivity are small enough and other circumstances are satisfactory. The fifth option consists of onsite storage pending availability of an appropriate disposal method. Table 4.1 shows the radionuclide concentrations specified for the disposal options.

**

The material present in the West Lake Landfill is a form of natural uranium with daughters, although the daughters are not now in equilibrium. As mentioned above, the average concentration of Ra-226 in the West Lake Landfill wastes is about 90 pCi per gram, which (considered by itself) falls into Option 4 of the BTP since Option 4 criteria are controlled by the Ra-226 content in the wastes (i.e., 200 pCi of U-238 plus U-234 per gram would be accompanied by 100 pCi of Ra-226 per gram). However, because of the large ratio of Th-230 radioactivity to that of Ra-226, the radioactive decay of the Th-230 will increase the concentration of its decay product Ra-226 until these two radionuclides are again in equilibrium. Assuming the ratio of activities of 100:1 used above, the Ra-226 activity will increase by a factor of five over the next 100 years, by a factor of nine 200 years from now, and by a factor of thirty-five 1000 years from now. All radionuclides in the decay chain after Ra-226 (and thus the Rn-222 gas flux) will also be increased by similar multiples. Therefore, the long-term Ra-226 concentration will exceed the Option 4 criteria.

^CConcentration based on limiting equivalent exposure to 0.02 WL or less.

dConcentrations based on limiting individual intruder doses to 500 mrem per year and, in cases of natural uranium, limiting exposure to Rn-222 and its decay product airborne alpha emitters to 0.02 WL or less.

5 REMEDIAL ACTION ALTERNATIVE CONSIDERATIONS

The radioactive material as it presently exists does not pose an immediate health hazard for individuals living or working in the area of the landfill. However, there is a long-term potential for the radioactive material to pose a health problem. Therefore, this section discusses six (A-F) possible courses of action, of which all but A and D are considered temporary. Option A, in which no remedial action is proposed, is unacceptable because the concentrations of radionuclides in the landfill will become too high; Option A is described for comparison purposes only. Costs are based on the Dodge Guide to Public Works and Heavy Construction, 1984.

5.1 Option A: No Remedial Action

Under Option A, no remedial work would be done on the West Lake site. The land-fill and the radioactive soil would be left in their present condition. The contaminated areas would be available for demolition fill emplacement and final closure. It is not certain how much additional fill would be emplaced. Filling would be followed by normal landfill closure operations.

Normal closure procedures consist of applying at least 0.61 m (2 ft) of compacted final cover. A 0.3-m (1 ft) layer of topsoil would be placed over the cover and upgraded to support vegetation. Establishment of a vegetative cover would require seeding, liming, and fertilization. Surface seeps of leachate would be eliminated. Maintenance of the monitoring wells would be required to allow continued sampling by MDNR, should MDNR require such action. The public would be discouraged from entering the site. After closure, a detailed description of the site would be filed with the County Recorder of Deeds. This description would include: a legal description of the site, types and location of wastes present, depth of fill, and description of any environmental control or monitoring systems requiring future maintenance (MDNR, January 1983). MDNR regulations also specifically prohibit excavation or disruption of the closed landfill without written approval of MDNR; no time frame is stated with this regulation (MDNR, 1975).

There would be no further cost under this option since no remedial actions would be taken; i.e., costs are normal landfill costs.

5.2 Option B: Stabilization on Site With Restricted Land Use

Two areas in the landfill contain radioactive material. Therefore, the work required for this option is described separately for each area. Nevertheless, restrictions would be imposed on the use of land within each area. This would discourage future activities on these areas which might expose individuals to radioactivity. No additional landfill would be permitted to be deposited on either area.

Area 1

It is believed that a total of 2 to 3 m (7 to 10 ft) of soil has been added to most of Area 1 since the 1981 land survey by RMC. This cover has altered the radiation environment of the site. Measurements by Oak Ridge Associated Universities (ORAU) personnel in March 1984 (Berger) showed that only a very small area exceeded the exposure rate of 20 µR/hr at 1 m. By extending the cover 20 m (66 ft) outward in all directions from the area showing an unacceptable surface exposure rate, the shallow wastes likely to give high rates of radon emanation will also be covered. The amount of radioactive debris in Area 1 is relatively minor compared with that present in Area 2. Therefore, a soil cover of 1.5 m (5 ft) is considered adequate to reduce surface exposure rates and radon emanation. After the soil cover is in place, a layer of topsoil 0.3 m (1 ft) thick would be emplaced, seeded, and mulched.

Area 2

Vegetation over Area 2 as well as on the slope of the berm would be cleared and placed in the demolition portion of the landfill or disposed of as is convenient. Brush should not be left in place and covered since this may reduce the integrity of the soil cap. Grass should be mowed, and may be left in place.

The berm on the northwest portion of the landfill which contains an estimated 7.500 m^3 (9.800 yd³) of contaminated soil would be excavated and redeposited in

layers in a secure portion of the landfill. The actual amount can be determined by survey during implementation of the work.

All equipment and materials now stored over Area 2 would be removed to other portions of the site or disposed of as is convenient to the owners. Gravel piles found on Area 2 should be removed to other portions of the site after having been surveyed to ensure that contaminants have not been mixed with the gravel. However, the lower 10 to 15 cm (4 to 6 in.) of rock should be left in place and covered with the soil cap, since this gravel may have become mixed with contaminated soil.

Such stabilization would place the contaminated soil well below the surface and would prevent radioactive materials from eroding as can now occur along sections of the berm. Stabilization would require emplacement of a soil cover of 48,000 m³ (63,000 yd³) to give a final slope of 3:1 with 1.5 m (5 ft) of soil at the top of the berm. At least 1.5 m (5 ft) of soil cover would be used, as this much soil will be required to reduce radon gas exhalation. The final slope of 3:1 on the berm would be shallow enough to prevent failure and, after the cover is emplaced, it should be further covered with at least 0.3 m (1 ft) of topsoil and seeded with native grasses to prevent erosion. The slope would be directed radially outward from the center of the cap. An interceptor ditch would be provided around the cap to channel runoff and prevent gullies from being cut into the stabilized cover. The cover soil presently used in the landfilling operations may be used to stabilize the berm. This soil is a clay silt (loess) excavated near the West Lake Landfill site.

The portion of Area 2 to be covered by the soil cap includes that portion of the landfill identified in the RMC survey as having surface exposure rates greater than 20 μ R/hr at 1 m (3.3 ft) above ground level, along with those areas in which auger holes revealed radium-bearing soil within 1 m of the surface. The shallow contaminants may be sufficiently shielded to produce low surface exposure rates; however, these shallow deposits will still produce radon emanations greater than the desired level of 20 pCi/m²s. Therefore, the soil cover must be extended over these areas of shallow contamination.

The cover soil used should be capable of compaction to a permeability of less than 10^{-7} cm/s in order to keep radon release and soil leaching as low as possible. This value is based on common practices used for sealing of hazardous waste landfills. Because accurately measuring permeability of this magnitude is difficult, the value of 10^{-7} cm/s should be used only as a target criterion which should, if possible, be bettered. If laboratory testing of the cover soil presently used at the West Lake Landfill indicates that this permeability can be achieved, this soil would be acceptable for use as the soil cap. Otherwise, clay soil would have to be imported from off the site to be used in constructing the soil cap.

The overall estimated cost for the required work under Option 8 is approximately \$360,000 (Table 5.1) and would require about 2 months to complete. Costs of this option may be higher if the total quantity of contaminated material to be moved is higher than the estimated quantity.

5.3 Option C: Extending the Landfill Off Site

Soil eroding on the northwest berm of Area 2 is carrying contaminated soil off the landfill property onto an adjacent cultivated field. A contributing factor to the erosion is the steepness of the berm. It would, therefore, be desirable to lessen the slope's steepness by extending the berm onto the adjacent field. This option would require the acquisition of approximately 2 ha (5 acres) of land not owned by the landfill company.

In this option, Area 1 would be treated the same as in Option B. The contaminated portion of the northwestern berm of Area 2 would not be disturbed. Instead the existing berm would be extended 13 to 16 m (42 to 52 ft) onto the adjacent field. This would require an additional solid volume of approximately 20,200 m^3 (26,400 yd^3) to give a final slope of 3:1 with 1.5 m (5 ft) of soil on top of the berm. As in Option B, this cover should receive an additional 0.3 m (1 ft) of topsoil and be seeded with native grasses to prevent erosion.

This option will require the relocation of three transmission poles. All other necessary work for Option C is as described for Option B.

The overall estimated cost for required work under Option C is approximately \$470,000 (Table 5.2) and would require about 2 months to complete. The extent of work required under this option is well defined.

5.4 Option D: Removing Radioactive Soil and Relocating It

This option would involve excavating and removing all contaminated soil and debris from the West Lake Landfill and relocating it to an authorized disposal facility.

Vegetation over Areas 1 and 2 would be cleared and placed in the demolition portion of the West Lake Landfill.

All equipment stored on the two contaminated areas would be removed to another portion of the site. Gravel piles in Area 2 should be removed. The lower 10 to 15 cm (4 to 6 in.) of rock should be left in place to be disposed of with other contaminated materials, since this gravel may have become mixed with contaminated soil at the surface.

The areas known to contain radioactive contamination at levels above the action criteria (20 μ R/hr at 1 m) would be excavated initially. Next, the excavated area would be surveyed to determine the extent of contamination remaining. Excavation would continue until unacceptable levels of contamination have been removed. Immediately after excavation, the soil would be placed in 208-liter (55 gal) approved drums (or other approved containers) for transport. Containment in the drums will prevent the spread of dust and loose soil during transport.

Some of the nonradiological hazardous material known to be present in the landfill could present a serious danger to workers should they excavate into this material. Proper precautions should, therefore, be taken as the work is being performed.

Estimated costs under Option D would be \$2,500,000 (Table 5.3). Transporting the contaminated soil to another site and emplacing the material there would significantly add to the cost. This option could be completed in about

3 months, providing that a suitable disposal facility were available to receive the contaminated waste.

5.5 Option E: Excavation and Temporary Onsite Storage in a Trench

Under this option, as much radioactive soil would be excavated as in Option D and would be placed in a specially prepared trench on the West Lake site but would not be placed in drums. This trench would become a temporary repository for the radioactive soil. The trench would be surrounded by an impervious clay liner to minimize leachate production and transport into the groundwater system. The cap should give acceptable rates of surface exposure and acceptable rates of radon gas release.

As under Option D, surface vegetation, machinery, and piles of crushed rock would be removed from the surface of areas to be excavated. Design of the trench is based upon the "secure landfill concept" (Shuster and Wagner, 1980) with three primary functions: eliminate direct gamma-ray exposure at the ground surface, reduce radon emanation, and prevent leaching of radionuclides to the groundwater system.

The excavated area would be cut to a maximum elevation of 140 m (460 ft) msl over the area to be covered by the trench. The base of the trench would cover an area 120×120 m (394 x 394 ft) and would have a negligible slope. Low spots would be filled with borrow soil* compacted to at least 90% of its standard Proctor density (SPD). Once the base for the trench has been leveled to a final elevation of about 140 m (460 ft) msl, a blanket of borrow soil at least 1.5 m (5 ft) thick compacted to at least 90% SPD would be emplaced. Specification of compaction of this underlayer is based on the requirement of avoiding subsidence which could cause the clay liner to crack and fail. A clay liner would be placed above the underlayer. The liner would be 0.5 m (1.6 ft) thick and would have a permeability less than 10^{-8} cm/s ($4 \times 10^{-9} \text{ in./s}$). An impermeable plastic liner could also be used.

^{*}Borrow soil refers to a clayey-silt loess (Soil Conservation Service type CL) excavated southeast of the site for use as daily cover in the landfilling operation.

Sides of the trench would be built at a 3:1 slope up to the level of the surrounding undisturbed landfill surface, about 143 m (470 ft) msl. The walls would consist of an underlayer and liner as described for the base. A layer of crusher-run limestone 0.5 m (1.6 ft) thick would be placed on top of the liner to allow leachate buildup in the trench to be monitored and to facilitate pumping should leachate buildup become a problem.

After the base and walls of the trench have been built, the previously excavated debris would be placed in the trench. Then the remaining radioactive debris would be excavated and placed in the trench. As excavation proceeds, it will become apparent how much volume the trench must have to contain all the contaminated soil. At this point, the walls of the trench would be raised to an appropriate level. Excavation and filling can then proceed until the work is complete. The final thickness of debris is expected to be from 4 to 6 m (13 to 20 ft).

A cover, as described below, would be placed over the debris. A 1 m (3 ft) layer of borrow soil compacted to 90% SPD will be placed over the debris. A clay liner 0.5 m (1.6 ft) thick of permeability less than 10^{-8} cm/s (4 x 10^{-9} in./s) would be placed over the borrow soil blanket. A 0.5-m (1.6-ft) layer of crusher-run limestone would be placed over the clay layer to prevent infiltration water from building up over the liner. A cover soil layer of average thickness about 2 m (7 ft) would be placed over the rock layer.

The cover soil would be compacted and built with a surface slope of from 2% to 4% to minimize erosion. Three-tenths of a meter (1 ft) of top soil would be placed over the cover layer and would be seeded and mulched to establish a vegetative cover.

Once the trench has been prepared to accept the soil, workers may begin to excavate contaminated soil. As under Option C, an initial excavation would remove the area of known contamination, and a cleanup phase would remove all soil containing radionuclide concentrations above an action level of 15 pCi/g Ra-226. As soon as the soil has been excavated, it would be hauled to the trench and emplaced. The contaminated soil should be sufficiently compacted to

prevent settling, to maintain the integrity of the soil cap. As fill is being emplaced, the pipe for a monitoring well would be extended upward from the base of the gravel underdrain. This well should be designed in a manner that would allow future installation of a pump for drawing off leachate should this become necessary.

Costs for Option E would be approximately \$2,150,000 (Table 5.4). The estimated costs vary somewhat, since the exact limits of excavation cannot be defined until work begins. This work would require approximately 4 months to complete.

5.6 Option F: Construction of a Siurry Wall to Prevent Offsite Leachate Migration

Under Option F, radioactive soil would be left in place at the West Lake site. The wastes would be stabilized by means of a soil cover (as under Option B) and a downgradient slurry wall would be built around the contaminated soil. The slurry wall would be intended to keep leachate from migrating off site. This remedial action would be somewhat more effective than Option B in reducing the potential for groundwater contamination. However, costs incurred would be substantially higher than those for Option B or C. Benefits would be nearly identical to those derived by the soil cover and berm stabilization alone; the sole advantage of Option F over Option B or C would be greater protection to groundwater in the Missouri River alluvium.

Vegetation, machinery, and piles of crushed rock would have to be removed as described for Option B. A slurry wall would be constructed by excavating a trench [approximately 1 m (3.3 ft) wide] to the depth of bedrock. This trench would be bored out in the presence of a mud weighted with bentonite (clay) to keep the walls from collapsing and to keep groundwater from intruding into the trench. The trench would be excavated in sections 6 to 8 m (20 to 26 ft) long. Once a section of trench has been excavated, concrete would be poured by tremie into the trench to displace the slurry. The final slurry walls would each consist of a concrete slab about 1 m (3.3 ft) thick extending to bedrock and partially encircling the bodies of radioactive soil in both Areas 1 and 2. A total of approximately 1300 linear meters (4,300 ft) of wall would be constructed to depths varying from 5 to 15 m (16 to 50 ft).

After each of the slurry walls had been emplaced, fill would be added along the face of the berm to stabilize the slope. Finally, a soil cover would be placed over the contaminated areas. The berm would be stabilized and the soil cover would be placed as outlined for Option B.

Costs of work required for Option F would be approximately \$5,600,000 (Table 5.5). The exact amount of slurry wall cannot be determined until work is begun; therefore, this cost will be highly variable. Since the walls should extend to bedrock, the depth of soil and landfill debris will govern the depth of the required wall. Slight errors in estimating the depth of alluvium could result in large errors in the cost estimate. It is estimated that it would take 6 to 8 months to complete this option.

This work was performed by EG&G for the United States Nuclear Regulatory Commission through an EAO transfer of funds to Contract No. DE-ACO8-76NVO1183 with the United States Department of Energy.

ABSTRACT

An aerial radiological survey to measure terrestrial gamma radiation was carried out over the Mallinckrodt Nuclear Maryland Heights Facility during October 1977.

At the same time the following properties were also surveyed: a parcel near 9200 West Latty Avenue, which included a portion of St. Louis International Airport; and land used by West Lake Landfill, Inc., which is 8 km northwest of the airport.

Gamma ray data were collected by flying parallel lines 60 m apart. The total area surveyed over the three sites was 7.4 km².

Processed data indicated that detected radioisotopes and their associated gamma ray exposure rates were consistent with those expected from normal background emitters, except at certain locations described in this report.

Average exposure rates 1 m above the ground, as calculated from aerial data, are presented in the form of an isopleth map. No ground sample data were taken at the time of the aerial survey.

1.0 INTRODUCTION

The United States Department of Energy (DOE) maintains an aerial surveillance operation called the Aerial Measuring System (AMS).* AMS is operated for DOE by EG&G. This continuing nationwide program, started in 1958, involves surveys to monitor radiation levels in and around facilities producing, utilizing, or storing radioactive materials. The purpose of the survey is to document, at a given point in time, the location of all areas containing gamma emitting radioactivity (visible at the surface), and to aid local personnel in evaluating the magnitude and spatial extent of any radioactive contaminants released into the environment. At the request of DOE, or other federal and/or state agencies (such as the United States Nuclear Regulatory Commission), AMS is deployed for various aerial survey operations.

AMS was utilized during the period 22-28 October 1977 to radiometrically survey an area 1.6 km² centered on the Mallinckrodt Nuclear Maryland Heights Facility. Also surveyed was an area 3.2 km² surrounding 9200 West Latty Avenue, which included a portion of the St. Louis International Airport A third site surveyed was a 2.6 km² area centered on property operated by West Lake Landfill, Inc., 8 km northwest of the airport.

The St. Louis International Airport was the survey base of operation.

2.0 SURVEY AREA HISTORY AND LOCATION

The Mallinckrodt Nuclear Maryland Heights Facility is located at 2703 Wagoner Place, St. Louis, Missouri. This plant receives radioisotopes from various vendors and converts them to radio pharmaceutical materials. Radioisotopes which they handle include ¹³¹I, ^{99th}Tc, ⁹⁹Mo, ⁷⁵Se, and ⁵⁹Fe. Mallinckrodt Nuclear is a Division of Mallinckrodt, Inc. (formerly, Mallinckrodt Chemical Works). Mallinckrodt, Inc. acquired the Maryland Heights facility from Nuclear Consultants, Inc. in 1965.

It is reported in an ORNL report² and a NRC report³ that during the period 1942 through the late 1950's Mallinckrodt Chemical Works of St. Louis processed uranium ore. Some of the ore

residues and processed wastes were stored on the airport property.

In early 1966 these ore residues and uraniumbearing processed wastes were moved from the airport property by the Continental Mining and Milling Company of Chicago, Illinois to the Latty Avenue site.

In January, 1967 the Commercial Discount Corporation of Chicago, Illinois purchased the residues; much of the material was then dried and shipped to the Cotter Corporation facilities in Canon City, Colorado. The source material remaining at the Latty Avenue site was sold to the Cotter Corporation in December, 1969. Records indicate that residues remaining on the site at that time included 74,000 tons of Belgian Congo pitchblende raffinate containing about 113 tons of uranium; 32,500 tons of Colorado raffinate containing about 48 tons of uranium; and 8,700 tons of leached barium sulfate containing about 7 tons of uranium. During the period August through November, 1970 Cotter Corporation dried some of the remaining residues and shipped them to their mill in Canon City. Colorado. By December, 1970 an estimated 10,000 tons of Colorado raffinate and 8,700 tons of leached barium sulfate remained at the Latty Avenue site.

In April, 1974 a NRC inspector was informed that the remaining Colorado raffinate had been shipped in mid-1973 to Canon City without drying and that the leached barium sulfate had been transported to a landfill area in St. Louis County. A reported 12 to 18 inches of topsoil had been stripped from the Latty Avenue site: this supposedly had been removed with the leached barium sulfate. However, analyses of soil samples taken during a NRC investigation of the Latty Avenue site in 1976 indicated the presence of uranium- and thorium-bearing residues.

The West Lake Landfill property is located off St. Charles Rock Road near Taussig Road, approximately 8 km northwest of the airport.

3.0 SURVEY METHOD AND AIRBORNE EQUIPMENT

An enlarged aerial photo of each site was used to lay out the survey flight lines (Figures 1, 2, and 3). The navigator visually directed the aircraft

^{*}Formerly Aerial Measuring System (ARMS).

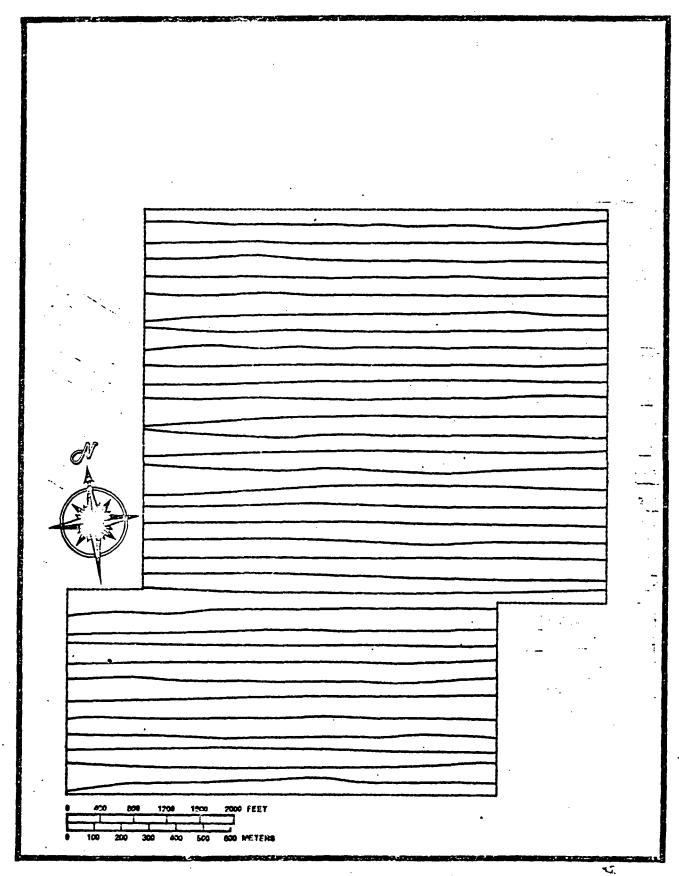

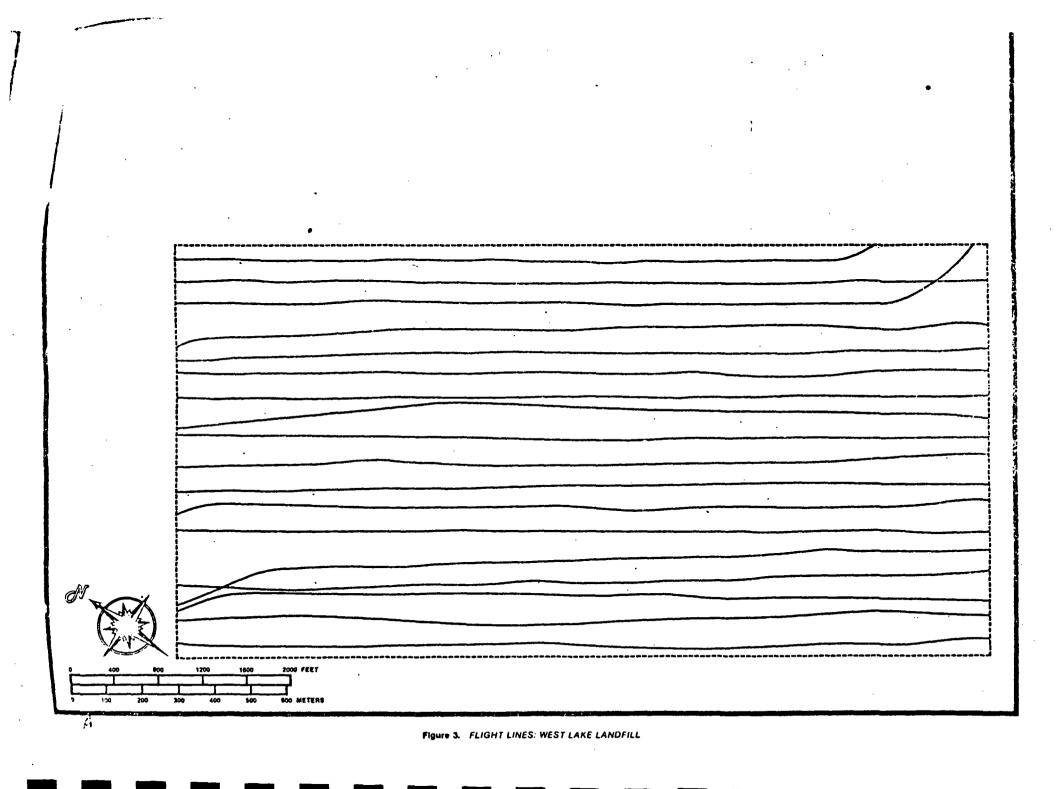

Figure 2. FLIGHT LINES: LATTY AVENUE

along the programmed flight lines on the photograph. The survey pattern consisted of parallel lines at 60 m intervals. Flight altitude was 60 m.

A Hughes H-500 helicopter was utilized for the survey (Figure 4). The H-500 carried a crew of two: pilot and navigator. The helicopter employed a lightweight version of the Radiation and Environmental Data Acquisition and Recorder system (REDAR). Two pods were mounted on the sides of the helicopter: each pod contained ten 12.7 cm diameter by 5.1 cm height Nal(Tl) detectors. Gamma ray signals from the 20 detectors were summed and routed through an analog-to-digital converter and a pulse-height analyzer. Gamma spectra were accumulated in 3-second intervals and recorded on 1/2 inch magnetic tape.

The helicopter position was established with two systems: a Trisponder/202A Microwave Ranging System (MRS), and an AL-101 radio altimeter. The trisponder master station

mounted in the helicopter interrogated two remote transceivers mounted on towers outside the survey area. By measuring the round trip propagation time between the master and remote stations, the master computed the distance to each. These distances were recorded on magnetic tape each second; in subsequent computer processing these were converted to position coordinates.

The radio altimeter similarly measured the time lag for the return of a pulsed signal and converted this to aircraft altitude. For altitudes up to 150 m, the accuracy was \pm 0.6 m or \pm 2%, whichever is greater. These data were also recorded on magnetic tape so that any variations in gamma signal strength caused by altitude fluctuation could be accurately compensated.

The detectors and electronic systems which accumulate and record the data are described only briefly here. They are described in considerable detail in a previous report.

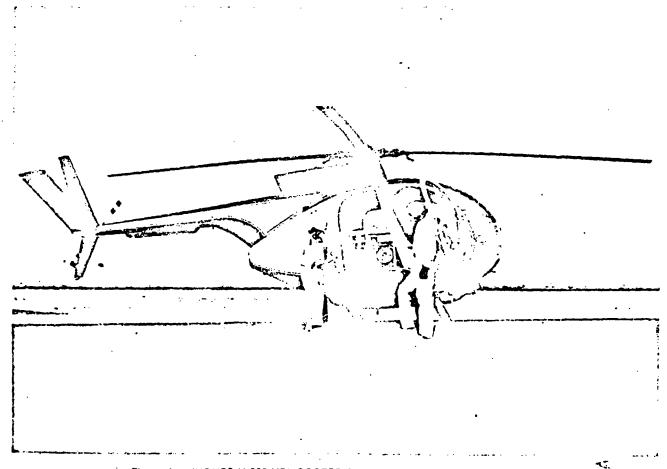

Figure 4. HUGHES H-500 HELICOPTER CONTAINING THE REDAR SYSTEM

A.D DATA PROCESSING

Data processing was done with the Radiation and Environmental Data Analyzer and Computer system (REDAC). This is a computer analysis laboratory mounted in a mobile van (Figure 5).

REDAC consists primarily of two Cipher Data tape drives, a Data General NOVA 840 computer, two Calcomp plotters, and a Tektronics CRT display screen. The computer has a 32 k-word core memory and an additional 1.2 x 10⁶-word disc memory. An extensive collection of software routines is available for data processing.

The gross count data were corrected for system dead time and altitude deviation. Corrections to the gross count rates were also made for contributions from radon, aircraft background,

and cosmic rays. Flights over the Missouri River were used for this purpose.

The corrected gross count rates were converted to exposure rates at 1 m altitude, with the factor 1024 counts per second (cps) per µR/h obtained from calibration data over a Nevada test range.

5.0 DISCUSSION AND RESULTS

Analysis of the radiological data taken over the area surrounding each of the sites discussed in this report indicates that the terrestrial radioisotopes and associated gamma ray exposure rates were consistent with the natural background normally found within areas having a similar geological basis. These background exposure rates were in the 8-11 μ R/h range, including 3.7 μ R/h due to cosmic rays.

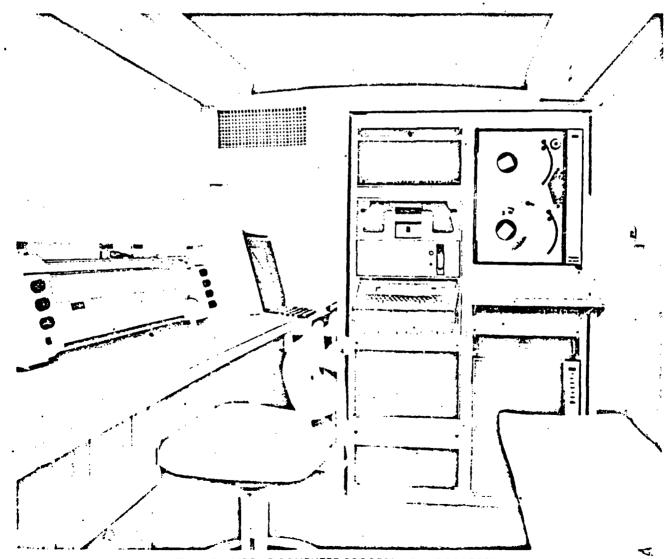

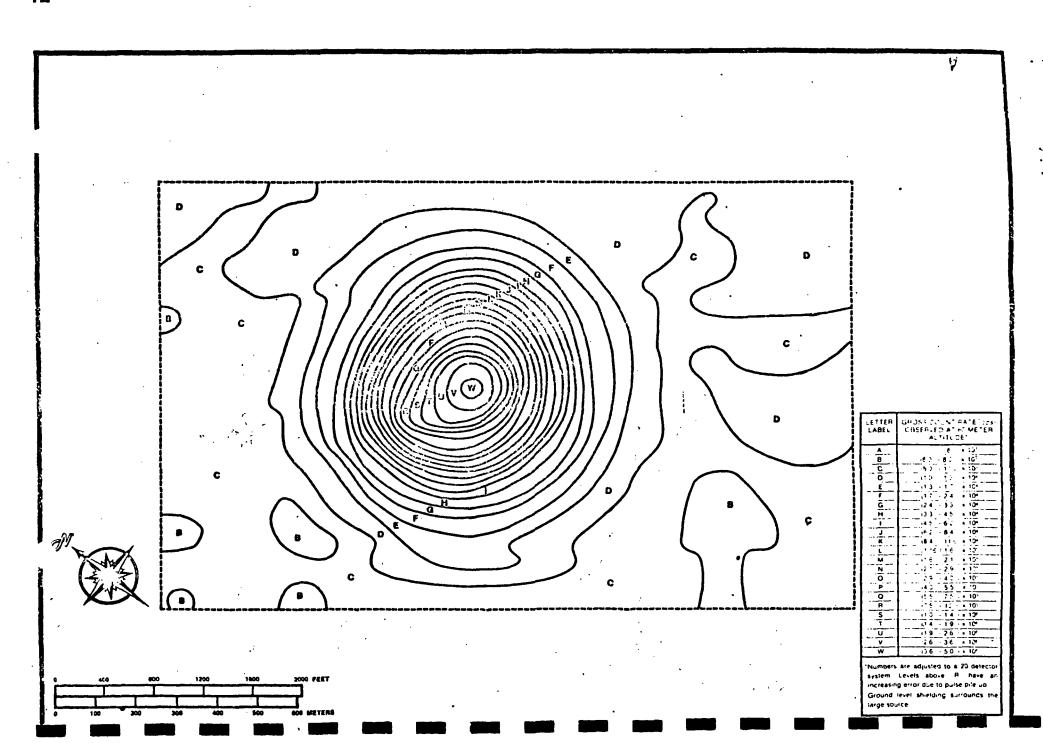

Figure 5. MOBILE COMPUTER PROCESSING LABORATORY

5.1 Mallinckrodt Nuclear.

Figure 6 presents gross count rate isopleths superimposed on an aerial photograph of the Maltinckrodt Nuclear Maryland Heights Facility. The isopleths shown in this figure are consistent with the existence of point sources in a storage room which has heavily shielded walls at the ground level but a lightly shielded roof. Due to this difference in shielding the aerially determined isopleths are not representative of what would be measured on the ground. For this

reason, and because conversion factors apply only to uniform horizontal distributions at the ground level, the letter labels in Figure 6 have not been converted to exposure rates at the 1 m level.

Figure 7 is a background-subtracted energy spectrum of the radiation from the area of increased activity. Photopeaks observed are 364 keV and 637 keV from ¹³¹I, 740 keV and 780 keV from ⁹⁹Mo, and 1.095 MeV and 1.292 MeV from ⁵⁹Fe. All three of these isotopes are received by the Facility for processing.

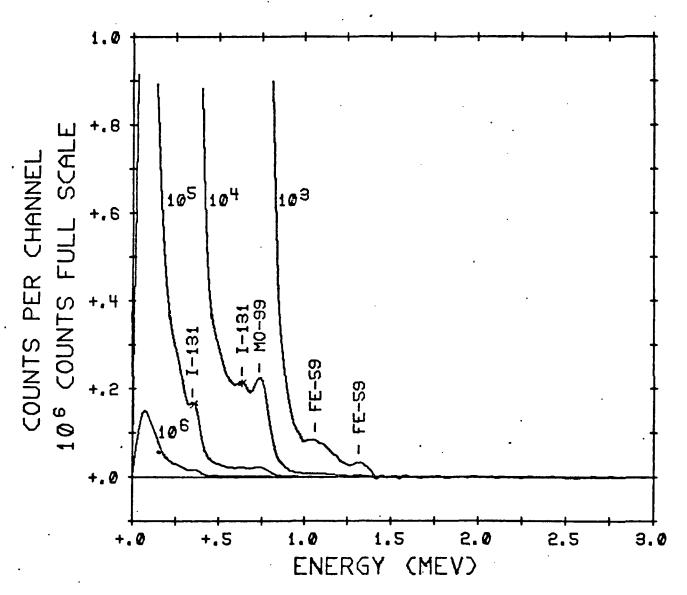

Figure 7. BACKGROUND-SUBTRACTED ENERGY SPECTRUM: MALLINCKRODT NUCLEAR SITE This spectrum characterizes the enhanced activity observed in Figure 6.

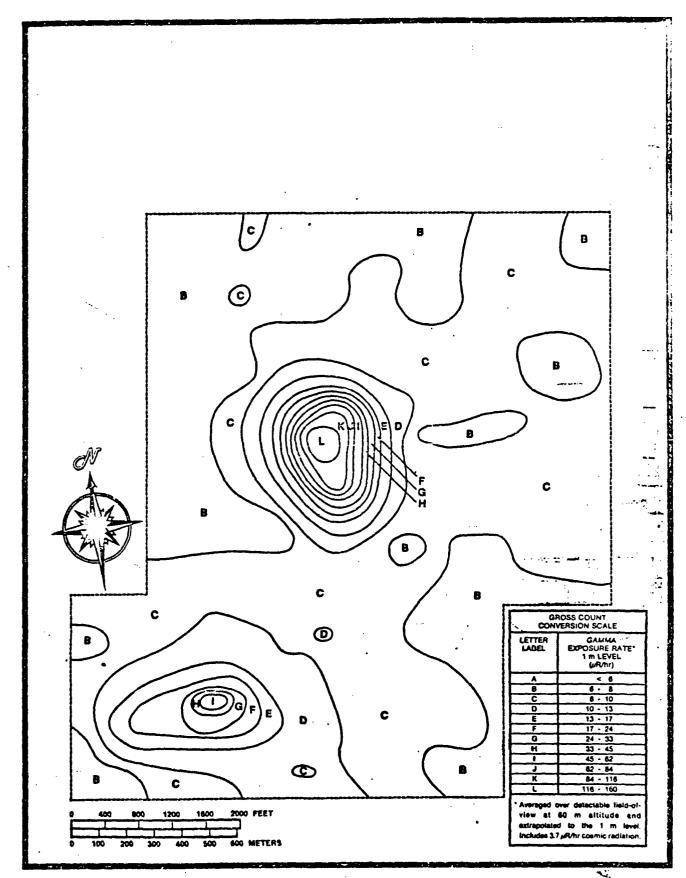

Figure & EXPOSURE RATE ISOPLETHS: LATTY AVENUE

5.2 Latty Avenue and Airport

Figure 8 presents the exposure rate isopleths superimposed on an aerial photograph of the site. Figure 9 is a background-subtracted energy spectrum of the radiation characteristics of both areas of increased activity. Radiation from ²¹⁴Bi accounts for all the major photopeaks observed.

This isopleth map (Figure 8) is based on gross counts (integral counts in the energy region

between .05 MeV and 3 MeV). The factor used to convert these counts to the exposure rate at the 1 m level was determined from measurements at a calibration site containing a typical mix of naturally occurring radionuclides. Since the spectrum shown in Figure 9 is different from a typical natural spectrum, the conversion factor may be in error. The isopleths, which represent ground level exposure rates for distributed sources, are consistent with sources whose lateral dimensions are a few hundred feet.

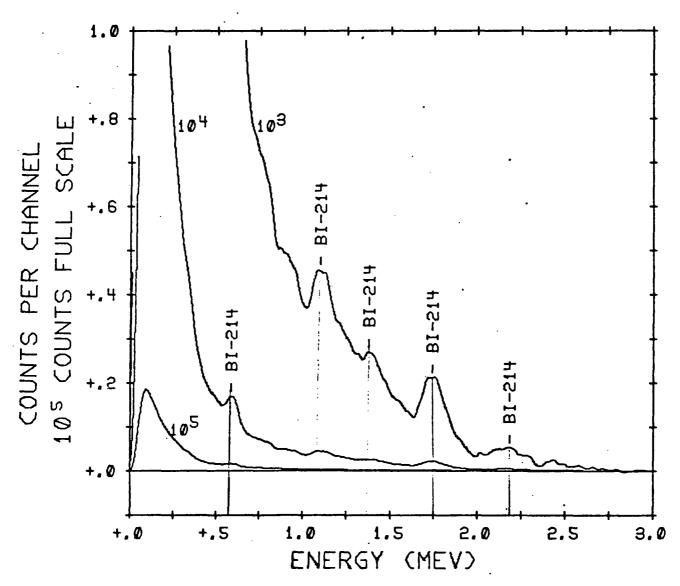

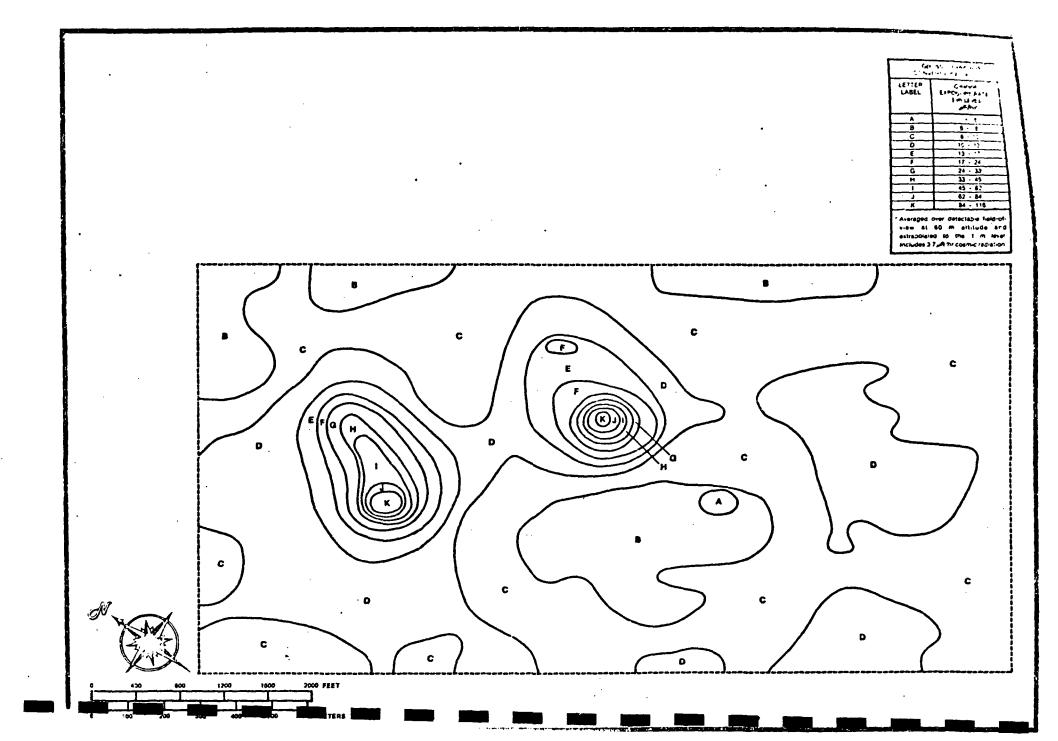

Figure 9. BACKGROUND-SUBTRACTED ENERGY SPECTRUM: LATTY AVENUE

This spectrum of gamma radiation was characteristic of the areas of increased activity at Latty Avenue and the airport as shown in Figure 8.

5.3 West Lake Landfill

Figure 10 presents the exposure rate isopleths superimposed on an aerial photograph of the site. Figure 11 is a background-subtracted

energy spectrum of the radiation characteristic countries both areas of increased activity. Radiation from 214Bi accounts for all the major photopeak observed.

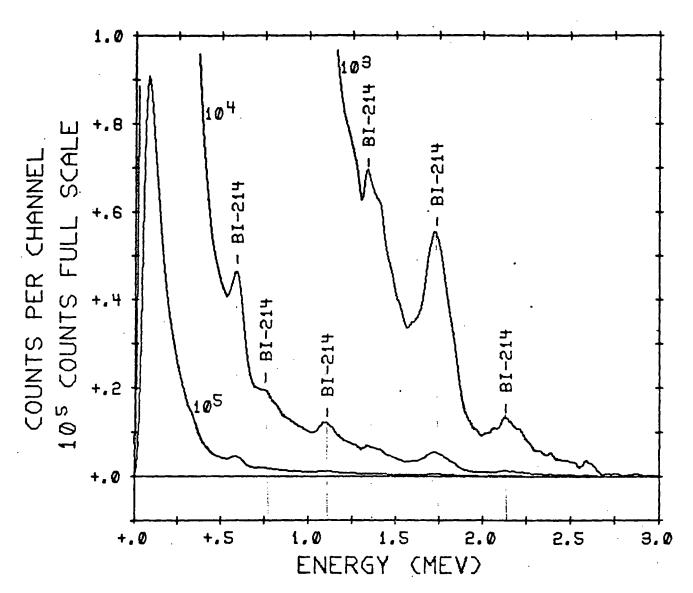

Figure 11. BACKGROUND-SUBTRACTED ENERGY SPECTRUM: WEST LAKE LANDFILL
Photopeaks shown here characterize both areas of enhanced activity in Figure 10.

RE: Phase II Site Investigation

Earth City Property Adjacent to West Lake Landfill

Dames & Moore Job No.: 19943-002-045

Dear Mr. Basilico:

Enclosed for your information are two (2) copies of the Phase II Site Investigation final report for the above referenced property.

Should you have any questions or wish to discuss this report in any way, please do not hesitate to contact Ms. Linda Black or myself.

Very truly yours,

DAMES & MOORE
A Professional Limited Partnership

1.0 INTRODUCTION

In April, 1990, Ford Financial Services Group, U.S. Real Estate authorized Dames & Moore to proceed with a Phase II Site Investigation to further document pre-transaction conditions at property adjacent to a proposed National Priorities List (NPL) site. This report presents a summary of the field techniques employed during this investigation and conclusions based upon analytical results from collected samples.

1.1 Executive Summary

The Phase II Site Investigation involved a more in-depth investigation of organic, inorganic, and radiological contamination of the Ford Property that is believed to be related to the adjacent West Lake Landfill. Upon review and evaluation of all information obtained from this investigation, several concluding remarks can be made which best summarize this effort.

First, the gamma radiation survey conducted on surface soils in areas north and west of the West Lake Landfill (i.e., areas which receive a large amount of surface runoff from the landfill) indicated that there is no significant surface radiological contamination present. Radiological contamination present within the landfill, therefore, does not appear to have contributed any significant contamination due to surface runoff to the 23 acres surveyed.

Second, in addition to the surface soil survey just described which required the use of a direct-reading meter, surface soil samples where also collected from 0-12 inches in depth from property locations adjacent to the landfill and submitted for more in depth chemical and radiological analysis. Soil samples were collected in locations where contamination was suspected from the Phase I effort and in locations where contamination might reasonably be expected. Although very low levels (parts per billion) of organic contamination were provided in the analytical report for the two soil sample composites, these values were actually below the analytical limit of detection and are, consequently, not significant. Of all the soil samples collected (a total of 20), only the samples collected from the two (2) locations where radiological contamination had been indicated from the Phase I investigation had radiological contamination (i.e., the biased samples). No further surface radiological contamination beyond these biased locations is evident based upon this information and the gamma radiation survey.

Third, sediment/soil samples were collected and analyzed from four (4) locations where chemical or radiological contamination might reasonably be expected to have migrated from the landfill via surface water. As with the soil samples, only low level organic chemical contamination was indicated which is likewise believed to be attributed to the sampling technique and not to actual soil contamination. Radiological contamination is also not evident in these samples.

Fourth, subsurface soil conditions were also surveyed radiologically down to groundwater in several locations to the north and west of the landfill. Gamma radiation and volatile organics were measured in soil borings down to groundwater using a GM-type survey meter and a photoionization detector, respectively. Neither radiological contamination nor chemical contamination of any type was evident.

Fifth, groundwater was sampled and analyzed chemically and radiologically by installing monitoring wells in the same soil borings that were mentioned previously. Low level (part per billion) concentrations of some organic chemicals were detected in several of the groundwater samples. Several of these, however, are believed to be attributable to background contamination from the laboratory, and as such, do not represent a significant environmental concern. Two semi-volatile BNAs (chrysene and Bis (2-ethylhexyl)phthalate) were, however, also detected in very low levels (1-27 ppb) in four (4) of the well samples. Other chemical contaminants tested for in the groundwater (i.e., metals, cyanide) were not present in sufficient concentration to represent a significant environmental concern. Although radiologically speaking there were conflicting results from the two laboratories used, there does not in any case appear to be significant groundwater contamination. The one parameter that was tested and found to be somewhat elevated in some of the water samples (gross alpha) is of secondary importance since the sum of the individual components that typically comprise this parameter failed to confirm the gross alpha totals.

With the exception of two (2) biased locations adjacent to the West Lake Landfill where radiological contamination is evident (B1 and B2), it is unlikely that the results provided from this investigation can be interpreted as evidence that the radioactive material resident in the West Lake Landfill has migrated to Earth City property.

1.2 Project History Summary

In December, 1989, Ford retained Dames & Moore to prepare an assessment of the radiologic conditions at their properties in Earth City, Missouri, as part of a pre-divestiture due diligence effort. The scope of the Phase I effort was primarily to respond to concerns raised by the proximity of the West Lake Landfill, located immediately to the east of the property under review (Figure 1). On October 23, 1989, the landfill was proposed for addition to the National Priorities List under CERCLA, due to improper acceptance during the early 1970's of radiologic materials primarily from the Department of Energy's Latty Avenue operations.

Upon completion of a review of available information, and a limited sampling effort, Dames & Moore concluded that the data suggests that significant off-site migration of radioactive contaminants from the landfill via groundwater has not occurred. However, it was recommended that surface contamination attributable to landfill runoff be further characterized.

This Phase II Investigation has been developed to document more extensively field conditions by means of additional soil and water sampling for an expanded set of parameters, believed to be more representative of potential landfill contents.

1.3 Scope of Work Summary

. The services performed during this Phase II investigation included the following five elements:

- Overland Gamma Survey Gamma radiation levels were measured at one centimeter and one (1) meter above the ground surface to ascertain whether additional areas of surface radioactive contamination exist;
- o Surface Soil Sampling Discrete and composite soil samples were collected in the two known "hot spots", in random areas, and in one background location;
- o Sediment Sampling Discrete sediment samples were collected from drainage areas likely to be influenced by runoff from the landfill;
- o Soil Borings/Downhole Gamma Logging Seven soil borings were advanced to 15-25 feet depths. Cuttings were screened for organic vapors and for radiation levels. Gamma radiation levels were also measured and recorded inside the borehole, advancing in six-inch increments to the water table; and
- o Groundwater Sampling Monitoring wells were installed at each of the borings. Samples were collected for laboratory analysis for organic, inorganic, and radiologic parameters.

2.0 OVERLAND GAMMA SURVEY

Between April 9 and 13, 1990, Dames & Moore personnel conducted an overland gamma radiation survey of 23 acres adjacent to the landfill which had not previously been surveyed. These measurements would indicate areas, if any, where radiation levels were elevated above ambient background.

2.1 Field Investigation

The overland gamma survey covered the areas shown on Figure 2. The area to the north of the landfill, and to a lesser extent, along Old St. Charles Rock Road were surveyed to assess potential migration of radiologic materials via surface routes. Areas adjacent to the recently excavated drainage ditch/lake were surveyed to assess the levels of radiation in the material dredged from the ditch, which may have intercepted potentially contaminated groundwater.

The gamma radiation survey was set up using a 10 x 10 meter survey grid to maintain reproducibility and accuracy. Each section was first marked with stakes, using the S66 48'41" E line, road coordinates, and chain-link fence which delineates the landfill, as the three primary reference lines. Section grid lines were established 90 degrees from the reference lines at 10 meter intervals. Three grids were established - the largest encompassed the area north of the landfill and covered approximately eight (8) acres. The second was established to the west of Old St. Charles Rock Road in an area of disturbed soils recently excavated from a nearby drainage ditch/lake. The third was also established west of Old St. Charles Rock Road and paralleled nearly the entire Ford/West Lake common boundary over an area of soils excavated from the nearby drainage ditch/lake.

Two calibrated Bicron microrem radiation survey meters were used for radiation level measurements at each intersection of the grid at one centimeter and one meter above the ground surface. These instruments use a tissue-equivalent plastic scintillator as the detection medium to provide accurate dose rate information relative to biologic tissue. An instrument operability check, which included a battery, background and source check was performed daily prior to use and several times during use, to assure property instrument operation while performing the survey. Both survey instruments were calibrated by the manufacturer and certificates of calibration are attached as Appendix A.

2.2 Investigation Results

Gamma radiation levels measured during the survey of the property are tabulated in Table 1. A map of the grid points is attached as Figure 3. Background radiation measurements were recorded from several areas off-site and in ambient areas located on-site. The average background dose rate for the two instruments in these areas ranged from three (3) to six (6) microrem per hour which corresponds with levels identified by ORNL in a study titled "State Background Radiation Levels 1975-1979" (report #TM-7343) which gives levels for the East St. Louis area of between four (4) and eight(8) microrem per hour. All measurements made on the property represented actual instrument readings without background data subtraction. Raw data tabulated in Table 1, represent readings obtained at each survey point one meter and one centimeter above ground surface. The primary reference point for each grid is indicated on Table 1 and the site map (Figure 3) as point 0,0. All tables give the survey point locations

based on their position relative to the reference point within the data matrix.

The U.S. Environmental Protection Agency guidelines for site cleanup and management of residual uranium and thorium (40 CFR 192, Subparts B & E) require that the exposure rate measured at a distance of one meter above the ground surface be less than 20 microrems per hour above background. In the case of the present survey, results did not exceed twice the measured background rate in any of the areas surveyed.

Contaminants located within the West Lake Landfill did not appear to influence the surface gamma radiation readings over the 23 acres surveyed. Although some fluctuations were present in the data, elevated gamma radiation readings within three times the average background measurement are not considered to be of consequence unless a systematic increase is noted. Site-wide trends were not readily apparent from the collected data.

3.0 SOIL SAMPLING

Surface soil samples were collected at several locations to characterize existing soil conditions in areas of the site adjacent to the landfill where contamination is suspected, and where contamination might reasonably be expected.

3.1 Field Investigation

Two composite soil samples (COMP-1 and COMP-2) were collected from the areas indicated on Figure 4 (shown as C1 and C2). It is believed that the soils dredged from the ditch along Old St. Charles Rock Road has been spread over these areas. These soils were therefore sampled to indicate whether any contaminants may have settled out from surface waters carried in the ditch. Each samples was collected from six points in the area shown, and submitted for analysis for total petroleum hydrocarbons (TPH), semi-volatiles, pesticides, PCBs, herbicides, metals, and cyanide, as well as radiological parameters.

Six unbiased soil samples (UB1-UB6) were collected at the locations shown on Figure 4. These areas were distributed along the general perimeter of the landfill to provide information regarding existing soil conditions. Each sample was collected at 0-6 inch depths and submitted for radiological analysis.

Biased soil samples were collected at two locations (B1 and B2) as shown on figure 4, which were identified during Phase I as having elevated gamma radiation levels. Samples B1A, B1B, B2A, and B2B were collected at 0-6 inch depths. Samples B1C and B2C were collected at 6-12 inch depths. All six samples were analyzed for several radiological parameters.

Samples were collected manually using either a stainless steel trowel or a stainless steel hand auger. Sampling equipment was decontaminated with Alconox detergent wash and a distilled water rinse between each sample.

Samples requiring radiological analysis were placed in plastic bags provided by the laboratory. Organic and inorganic samples were placed in jars provided by the laboratory (Table 2). Organic and inorganic samples were placed in an iced cooler. All samples were shipped to the respective laboratories via overnight delivery accompanied by Dames & Moore chain-of-custody records (Appendix B).

3.2 Investigation Results

A summary of organic and inorganic data is presented in Table 3. For nearly all parameters, there are no indications that samples COMP1 and COMP2 vary significantly from the background sample BKG.

Exceptions of note are the results of analyses for semi-volatile compounds. No semi-volatiles are indicated in the background sample, however, two compounds were detected in COMP1 and six compounds were detected in COMP 2. The semi-volatile compounds detected in the composite samples have been attributed to the sampling technique, which involved mixing the composite inside a plastic zip-lock bag. The background sample was collected directly into sample jars without contact with a bag.

A summary of the radiological data for soil samples is presented in Tables 4A, 4B, 4C, and 4D. All values are reported in units of picocuries per gram of sample plus or minus the error associated with the analysis at a 95 percent confidence level (± 2 sigma). All soil samples were analyzed for gross alpha and gross beta content and the specific nuclides uranium-234, 235/236, 238; thorium-230,232; potassium-40; cesium-137 and radium-226, 228. Values reported as less than (<) a specific value, are considered below the analytical instrument's lower limit of detection. Table 4A shows that the analytical results reported for unbiased samples UB1 through UB6 are indistinguishable from the background sample collected at the same depth as well as background samples analyzed for the Phase I investigation. Biased samples collected in the two areas identified as above background in the Phase I investigation, show, as expected, elevated gross alpha and gross beta.

For area 1 (Table 4B) gross alpha and gross beta for biased samples are elevated by factors of 55 and 10.6 respectively, while for Area 2 (Table 4C) levels are elevated by factors of 200 and 31, respectively. Similarly, elevated levels of uranium-234 and 238 are reported at 6.5 and 6 times background (Table 4B) and factors of 13.3 and 8.1, respectively (Table 4C). Thorium-230 values in sample B1A and B1B average over 400 times background, while B2A and B2B average over 900 times background. Thorium-232 however averaged only 3 times and

6 times background for areas 1 and 2, respectively. Ra-226 concentrations in the biased soil samples analyzed from areas 1 and 2 averaged 31 and 34 times background respectively. The above results refer only to the data reported for the 0-6" sample depth. The reported concentrations for the above mentioned nuclides in the 6-12" depth are equally elevated for the area 1 sample but are somewhat lower for the area 2 sample.

Composite soil sample results reported in Table 4D are indistinguishable from background.

4.0 SEDIMENT SAMPLING

Sediment samples were collected at four locations at the site to characterize existing conditions in areas where contamination might reasonably be expected to have migrated via surface water.

4.1 Field Investigation

Four sediment samples (S1-S4) were collected at the locations shown on Figure 5. Samples S1 and S2 were collected from the bottom of the drainage ditch which runs along Old St. Charles Rock Road. These samples were analyzed for several radiological parameters.

Sample S3 was collected from the bottom of a ponded area near St. Charles Rock Road. Sample S4 was collected from beneath the outlet of a surface water drain which originates at the base of the landfill berm, and emerges from the embankment of Old St. Charles Rock Road. Both samples were analyzed for organic and inorganic as well as radiological parameters.

Samples were collected using either a stainless steel trowel or a stainless steel hand auger. Sampling equipment was decontaminated with Alconox detergent wash and a distilled water rinse between each sample.

Radiological samples were placed in plastic bags provided by the laboratory. Organic and inorganic samples were placed in jars provided by the laboratory (Table 2). Organic and inorganic samples were placed in an iced cooler. All samples were shipped to the respective laboratories via overnight delivery accompanied by Dames & Moore chain-of-custody records (Appendix B).

4.2 <u>Investigation Results</u>

A summary of organic and inorganic data is presented in Table 5, as a comparison with background soil sample BKG. For nearly all parameters, there are no indications that samples S3 and S4 vary significantly from the background sample. Mercury was detected only in sample S4, at 0.18 ppm only slightly above the reported detection limits.

- Semi-volatile analytical results are similar to the soil samples, where several compounds were detected. Again, this is attributed to the sampling technique which involved mixing of the composite sample inside of a plastic zip-lock bag. The background sample was collected directly into sample jars without contact with a bag.

A summary of the radiological data is presented in Table 6. Review of this table shows that, for the radiological parameters specified, all data is indistinguishable from background except for the gross alpha value of sample S4 which is reported as 6.6 times background. Upon reanalysis of this sample by ITC, however, a much lower gross alpha value was obtained. For reasons explained in Section 7.1.3 of this report, the second analysis, which indicated a gross alpha level of 19.3 ± 8.6 , is considered to be more valid.

5.0 SOIL BORINGS/DOWNHOLE GAMMA LOGGING

Soil borings were advanced at seven (7) locations at the site to observe and assess subsurface soil conditions to the depth of the groundwater table. Additionally, gamma radiation was measured inside each borehole to provide vertical profiles of radiation levels.

5.1 Field Investigation

Soil borings were advanced to the groundwater table at seven locations shown on Figure 6, using an ATV-mounted hollow-stem auger drill rig. Samples were retrieved using a 3-inch diameter continuous sampler. Downhole drilling equipment was decontaminated between borings by pressure washing with water.

Geological observations made of the retrieved soils were maintained on Soil Boring Logs presented in Appendix D. Retrieved soils were field screened for VOCs with a photo-ionization detector, and for radiation levels with a G-M type survey meter.

Gamma radiation levels were measured inside the auger stem using an Eberline ESP-2 ratemeter and shielded SPA-3 scintillation detector. The detector was advanced in six-inch increments to depths approaching groundwater. Gamma logging measurements are shown in Tables 7-101 through 7-107, with graphical presentations in Figures 7-101 through 7-107.

5.2 Investigation Results

Borings depths ranged from 15 to 25 feet depending on the depth to groundwater. Soil types varied from silty to sandy silt, typically becoming coarser with depth. Some stiff silt or clay was noted. No volatile compounds were detected at any depth in any boring. Radiation levels were consistent with background levels.

All gamma logging data was consistent with background levels.

6.0 GROUNDWATER MONITORING

Groundwater monitoring wells were installed in each of the seven (7) soil borings at the locations shown on Figure 6. Well construction details are described in Section 6.1 and diagramed in Appendix E. Ten samples were collected for laboratory analysis according to the techniques discussed in Section 6.2. Analytical results are discussed in Section 6.3.

6.1 Monitoring Well Installation

As described in Section 5.0, soil borings were advanced by hollow stem auger. Upon completion of each boring, a 10-foot length of 2-inch diameter 0.010 slotted PVC well screen was placed to the bottom of the boring. PVC riser pipe was extended above the ground surface. A sand filter-pack was placed about the well screen as the auger flights were gradually removed from the borehole, typically to 2-feet above the top of the screened interval. A 1.5 - 2 feet thick bentonite pellet seal was placed above the sand pack. In wells MW101 and MW102, a cement slurry with a bentonite additive was placed from the top of the seal to a few feet below ground surface. At all wells, a cement-aggregate mixture was placed to the ground surface to secure the steel well protector, and to form a small concrete pad to deflect surface water away from the well. The PVC riser was fitted with a PVC screw cap and a padlock was placed on the steel protector. Well construction diagrams are shown in Appendix E.

Efforts by drilling contractor Brotcke to develop MW104 on April 12 using a tank of compressed nitrogen to drive an air-lift system were not successful. On Friday, April 13, 1990, personnel returned to develop the wells using an air compressor to drive water from the well. Purging efforts were continued for 30 minutes at each of the four wells (MW101, MW102, MW103, and MW104). The three remaining wells were not accessible due to wet ground conditions, and were developed by bailing.

6.2 Sample Collection

Groundwater sampling was conducted by Dames & Moore personnel on April 17 and 18, 1990. The following procedure was used at each well.

The depth to water from the top of the PVC casing was recorded to the nearest 1/16" using a chalked steel-tape. Standing water was purged from the well using a disposable polyethylene bailer (Voss Technologies). After removing one well volume, field measurements of temperature, pH and specific conductivity were made using a calibrated Hydac meter (Cambridge Scientific Industries) outfitted with an Orion pH probe. Field measurements were taken following each subsequent well-volume purged until three successive sets of measurements fell within the following ranges:

Temperature:

+/- 0.5° C

pH:

+/- 0.1 pH unit

Conductivity:

+/- micromhos

Typically, four (4) or five (5) well volumes were sufficient to accomplish stabilization. Field measurements are summarized in Appendix F. Based on contaminant levels during soil boring activities, purged water was discharged to the ground surface.

Upon stabilization, water samples were collected for laboratory analysis. Table 8 shows the volumes collected and preservations used to constitute one sample.

Samples were shipped via Federal Express to the appropriate laboratories for analysis (MW109 was hand delivered to Envirodyne), under Dames & Moore chain-of-custody procedures (Appendix B). Organic and inorganic samples were shipped in iced coolers. Each day, all VOA sample vials were placed in the same cooler, and were accompanied during shipment by trip blanks (TR-1 and TR-2).

6.3 <u>Investigative Results</u>

Data from organic and inorganic analyses are summarized in Table 9. Data packages from Southwest Laboratories and Envirodyne Engineers are provided in Appendix C. Data from the radiological analyses are summarized in Table 10. Data packages from ITC and CEP are provided in Appendix B.

A review of the organic and inorganic data indicated that pesticides, PCBs, herbicides, and cyanide were not detected. Several VOCs were identified near or below detection levels. Methylene chloride was detected at low levels (1-26 ppb) in all samples analyzed by Southwest. Similarly, acetone was detected (3-17 ppb) in most samples. Both compounds were detected in

the Southwest QA/QC method blank, and are frequent laboratory contaminants. The absence of these compounds in the Envirodyne analysis of MW109 (duplicate of both MW102 and MW108), reinforces the interpretation that the methylene chloride and acetone results are not accurate. Low levels of 1-1 dichloroethane are indicated in well MW102 and MW109 (3 ppb and 6 ppb, respectively). Toluene, ethyl benzene, and xylene were indicated in well MW103 in low levels also.

Two BNA (binuclear aromatic) compounds, chrysene and bis (2-ethylhexyl) phthalate, were also indicated in low levels in four (4) of the monitoring wells. Bis (2-ethylhexyl) phthalate was present in MW102, MW105, MW106, and MW109D while chrysene was present only in MW102.

Several metals were detected at low levels as well. Copper and zinc were consistently indicated in samples analyzed by Southwest. Antimony and nickel were also indicated in approximately half of the samples by Southwest. EEI/TCT reported the presence of arsenic, mercury, selenium, and silver in the two samples which they had analyzed (MW109 and MW109D). While there is a wide disparity in the metals results presented by the two laboratories, none of the actual reported quantities are at significant levels to be of concern.

Results of radiological analyses for groundwater samples collected during the Phase II investigation are reported in Tables 10A through 10D. Due to the propensity of groundwater samples collected from wells to contain filterable soil particulates which can skew results, all samples were analyzed as raw unfiltered water and as filtered water using a 0.45 micron filter medium. All results are reported as picocuries per liter of sample plus or minus the 2 sigma associated error. Numbers reported as less than (<) the reported value are below the limit of detectability for the given nuclide and analytical method. All results reported for filtered samples are indistinguishable from background data as represented by the off-site well water results of Table 2 in the Phase I report. Further, the filtered data would easily meet all existing radiological limits established for drinking water by the EPA (40 CFR 141). Of the unfiltered results four samples (MW-103U, MW-105U, MW-106U, and MW-107U) would not meet the EPA gross alpha criteria of 15 pCi/I for drinking water, but would meet all other established limits. However, since raw unfiltered groundwater would not be acceptable as drinking water, this comparison serves no purpose.

7.0 CONCLUSIONS

7.1 Radiological Investigations

7.1.1 Overland Gamma Survey

The results of the overland gamma survey discussed in Section 2 of this report clearly show that all areas surveyed were indistinguishable from ambient radiation levels associated with

nearby off-site locations. This conclusion is further supported by the results of the unbiased and composite soil sample analyses which were also indistinguishable from background radionuclide concentrations for the Phase II investigation area.

7.1.2 Soil

As discussed above, all unbiased and composite soil samples collected randomly within the 23 acres area of investigation, were found to have radionuclide concentrations similar to those measured for samples representing ambient (background) conditions collected for the present study, and those collected as background samples for the Phase I investigation. With regard to the two biased samples (B1 and B2) where contamination is evident, refer to Section 7.1.5 for details.

7.1.3 Sediment

Comparison of sediment samples to background soil samples collected for Phase I and II shows that all sediment results reported are less than or equal to the corresponding background concentration with the exception of the gross alpha result reported for sample S4. This sample was subjected to reanalysis of only the gross alpha parameter by ITC and the result reported to Dames & Moore, shown in Table 11, was 19.3 ± 8.6 . The original S4 gross alpha value was not confirmed by the reanalysis. This makes the initial analytical result a highly suspect data point, in that, several of the individual nuclides analyzed are alpha emitters, namely U-234, 235/236, 238, thorium-230 and 232 and radium-226. These nuclides are by far the most abundant alpha emitters in nature and therefore their sum should represent the majority of the gross alpha activity present. Because the sum of the individual nuclides is only 7.2 pCi/g, and the analytical techniques used to measure the individual nuclides is more precise than the gross alpha measurement, especially for a medium such as soil, the gross alpha measurement must be considered of secondary importance. Further, naturally occurring nuclides which are decay products of the marker nuclides may add to the gross alpha concentration, but are considered to be in equilibrium with their parent nuclide and therefore would not add significantly to the above calculated alpha contributions of the individual nuclides.

7.1.4 Groundwater

As discussed in Section 6.3, groundwater samples were analyzed as unfiltered and filtered to provide information on the quantity of filterable, and therefore undissolved particulates, resident in the samples. All results reported in Tables 10A through 10D for filtered samples easily meet EPA drinking water standards for gross alpha (15 pCi/l), gross beta (50 pCi/l) and radium-226 + 228 of 5 pCi/l. Further, all unfiltered samples meet these criteria except for the

gross alpha values reported for sample MW103-U, 17.2; MW105-U, 16.9; MW106-U, 101; and MW107-U, 202 pCi/l. The gross alpha values reported for these unfiltered samples are also of secondary importance since the sum of the individual nuclide concentrations fail to confirm the gross alpha values (see Section 7.1.3).

Groundwater sample MW102 was also subjected to quality assurance checks having a sample duplicate analyzed and a sample split analyzed by an independent laboratory. The results of both tests confirm the results of the original analysis as reported by IT Corporation. Most values for all tests were reported as below the limit of detection.

7.1.5 Biased Soil Samples

To provide additional characterization of the two limited hot spot areas identified during the Phase I study, the survey team was directed to resurvey the original areas, reidentify the location providing the highest gamma radiation level and remove 2-6" soil samples to a total depth of 12" to provide preliminary characterization of the nuclides present. These data are reported in Tables 4B and 4C.

For Area 1 (Tables 4B) the major nuclides identified as significantly above background are Th-230, Ra-226, U-234, and U-238. These results are confirmed in the sample duplicate analyzed by ITC and in the sample split analyzed by CEP except for Th-230. The discrepancy in the results is due to the differences in analytical techniques used by the two laboratories. Selected analytical results reported for original samples in Table 4B were reanalyzed with results shown in Table II. The reanalysis confirmed the original test results.

For Area 2 (Table 4C), the analytical parameters and major nuclides identified as present in concentrations more than 3 times background were gross alpha, gross beta, Th-230, U-234, U-238, and Ra-226.

Again for sample B2A, as for B1A, the duplicate of the original sample analyzed by ITC confirmed the initial results. The split sample with CEP again did not identify Th-230 in similar quantities, nor were gross alpha and gross beta results reported by CEP similar to the ITC data. Both laboratory technique and measurement capability differences are responsible for these discrepancies. Regardless of the CEP results, any regulatory bodies which would govern cleanup of the area would consider the highest reported results for regulatory purposes and therefore the CEP data splits would become meaningless. Further, this round of soil sampling would only serve to establish the highest potential concentration of nuclides in the area based on surface gamma radiation results. Further area characterization would be required to determine the vertical and horizontal extent of the contamination before clean-up activities could proceed. Due to the elevated levels of uranium-234 and 238 as well as radius-226 in these biased samples it is likely that this material originated from the West Lake Landfill property and found its way

to the present location via surface water erosion.

7.2 Inorganic and Organic Chemical Investigation

During the course of the Phase II investigation of the Earth City property, several different classes of both organic and inorganic contaminants were tested for in adjacent surface soils, groundwater, and drainage ditch bottom sediment. Organic contaminants tested for included total petroleum hydrocarbons (TPH), semi-volatile organics, pesticides, PCBs, herbicides, and volatile organics (VOCs). Inorganic contaminants tested for included metals and cyanide.

7.2.1 TPH

Surface soil composite samples (2) collected from areas adjacent to the West Lake Landfill had TPH levels below background. Sediment samples (2) collected from the bottom of a ponded area near the St. Charles Rock Road and from beneath the outlet of a landfill surface water drain, likewise had TPH levels below background.

7.2.2 Semi-volatiles

Low level concentrations (10-50 ppb) of several semi-volatile organic compounds were detected in both surface composite soil samples. Their presence is attributed to the sampling technique, which involved mixing the composite inside a plastic zip-lock bag. Plastic bags of this type often contain residual low level semi-volatiles. The sediment samples likewise contained low level semi-volatiles (10-19 ppb) which can be attributed to sampling technique.

Two semi-volatile BNAs, chrysene and bis (2-ethylhexyl)phthalate were detected in levels near or below detection limits in one and three monitoring wells, respectively, and do not represent a significant environmental concern.

7.2.3 Pesticides, PCBs, Herbicides, Cyanide

There were no detectable levels of any of these contaminants in any of the three sampling media.

7.2.4 VOCs

Volatile organics were tested for only in the eleven (11) groundwater samples. Two (2) VOCs, methylene chloride and acetone, were present in low concentrations in virtually all groundwater samples tested. These samples were analyzed by Southwest Laboratory and both of these VOC components, which are frequent laboratory contaminants, were detected in Southwest's QA/QC method blank. Consequently, this provides further evidence that the results for these contaminants are due to background contamination from the laboratory environment and as such, are not valid.

7.2.5 Metals

For both the soil sample composites (2) and the sediment samples (2), all metals detected do not vary significantly from background levels. Groundwater samples were analyzed by two separate laboratories: Southwest Laboratory and EEI/TCT. Low concentrations of copper, zinc, antimony, and nickel were detected by Southwest while EEI/TCT detected very low levels of arsenic, mercury, selenium, and silver. None of the levels detected represent a significant environmental concern.

REPORT OF ANALYSIS

CLIENT: Mr. Dave Purington

Dames & Moore

11960 Westline Ind. Drive

Suite 155

St. Louis, NO 63146

PROJ. #: 3500-00385

REPORT DATE:

May 10, 1990

SAMPLE ANALYZED: One water sample analyzed

for the parameters

listed below.

DATE RECEIVED:

April 18, 1990

P.O. 1:

PARAMETER UNITS		HW109	MW109 DUPLICATE
ANTIHONY	(DG/L)	< 24	< 24
ARSENIC	(UG/L)	3.1	2.5

David Purington DAMES & MOORE 11701 Borman Drive, Suite 340 St. Louis, Missouri 63146

Project: 19943 - 002; Ford Earth City

Dear Mr. Purington:

Enclosed are the analytical results for your samples received in our laboratory on April 17, 1990, for the above captioned project.

All the samples were originally extracted on April 17, 1990. The acid surrogates were outside QC limits for sample MW105, MW106 and MW107. These samples were re-extracted on April 26, 1990 and re-analyzed on May 1, 1990. The acid surrogates also did not meet the recovery criteria for sample MW105 and MW106. This indicated a matrix effect. We have reported the data from the reanalyses for these three sampls.

Per your request we have preformed a matrix spike and duplicate for the following samples;

MW101 (cyanide), MW105 (metals)

Additional Matrix Spike/Matrix Spike Duplicates will follow with the completion of the remaining portion of this project.

If, in your review, you should have any questions or require additional information, please call.

Sincerely,

Randy Staggs Project Manager

DAMES & MOORE

MAY 08 1990

ST. LOUIS, MISSOUT

David Purington
DAMES & MOORE
11701 Borman Drive, Suite 340
St. Louis, Missouri 63146

Project: 19943 - 002; Ford Earth City

Dear Mr. Purington:

Enclosed are the analytical results for your samples received in our laboratory on April 18, 1990, for the above captioned project.

Sample MW110 was originally extracted on April 19, 1990. The QC/MS analysis indicated that the surrogates did not meet the QC criteria. Hence, this sample was re-extracted on April 24, 1990, and later re-analysed. The data was reported for the re-analysed sample.

Per your request we have preformed a matrix spike and duplicate for the following samples; MW102 (semi-volatile), MW108 (Herbicides), MW110 (Pesticides), MW104 (Volatile)

If, in your review, you should have any questions or require additional information, please call.

Sincerely,

Randy Staggs

Project Manager

ALUES OUTSIDE OF QC LIMITS

May 3, 1990

Dave Purington DAMES & MOORE 11701 Borman Drive St. Louis, MO 63146

Project: Earth City

Dear Mr. Furington:

Enclosed are the analytical results for your samples received in our laboratory on April 13, 1990, for the above-captioned project.

If, in your review, you should have any questions or require additional information, please call.

Sincerely,

Randy Staggs Froject Manager

MEMORANDUM

Date:

October 2, 1980

To:

Bob Schreiber

From:

Burt McCullough

Subject:

Westlake Landfill

Mufing nu With lake

1980

SCLID WASTE HAR TOTATED PROCESM

Westlake Landfill, located in Bridgeton Missouri (St. Louis County) has been the subject of recent inquiry. This landfill began operation prior to state regulation. As far as our records show, this landfill first opened in the mid-1960's. Part of the landfill lies in an old quarry and part of the landfill lies in the Missouri River floodplain, approximately l_2^1 miles from the river. Witnesses to this operation, when the area of the landfill which lies in the floodplain was in operation, note that the fill area was often actually beneath the level of the water table. According to file materials from Missouri Geological Survey, it is "highly probable that leachate from the landfill is entering the waters of the Missouri River. . . " Leachate from the old quarry area of the landfill is collected and hauled to MSD treatment plants. Construction of onsite treatment facilities is underway. About 48,000 gallons of leachate per day is currently being collected.

Aside from normal landfill materials, there are chemical industrial wastes and radiologically contaminated materials deposited in this landfill. The chemical wastes, that we know of, include about 4,000 tons of residues from the production of insecticides and herbicides. These pesticide wastes were deposited by Chevron Chemical Company. Also included in the chemical wastes are waste materials from ink manufacture and from the manufacture of glue. Among the chemical wastes that we know of in Westlake Landfill are:

waste ink esters

pigments alcohols oily sludges insecticides

halogenated intermediates

aromatics

oils

wastewater sludges

heavy metals

asbestos

herbidices

Besides chemical hazardous wastes, in Westlake Landfill, there are radioactive wastes. During early 1973 Cotter Corporation buried radioactive Barium Sulfate Slag material and radiologically contaminated building rubbis. There are approximately 9,000 tons of this material which contain about 7.000 tons of natural Uranium. In October, 1977, an aerial radiological survey was done to determine the location of the burial of this contaminated material. The report from this survey indicates that there are two burial sites. One is in the center of the old quarry area, and the other is on the edge of the floodplain area which borders adjacent farmland. The U.S Nuclear Regulatory Commission has contracted Radiation Management Corporation to do extensive on-site radiological surveys which include groundwater analysis, core sampling, test boring, and other tests as deemed necessary. The NRC has given DNR verbal

permission to utilize the monitoring wells which Radiation Management Corporation will be digging, in order that DNR may test for the presence of chemical hazardous wastes.

There is little known about what went into Westlake Landfill prior to State regulation. Analysis needs to be done to determine: 1) what wastes are deposited in Westlake Landfill, 2) if any of these pollutants are leaving the landfill via groundwater, and 3) what threat does Westlake Landfill pose to drinking water supplies.

BUREAU OF BOLID WASTE MANAGEMENT

Mr. William Canney
West Lake Landfill, Inc.
Rt. 1, Box 206
Bridgeton, WO 63044

Dear Mr. Canney:

This is to follow up on the inspection of the West Lake Demolition Landfill on October 4, 1977, by a representative of the Missouri Department of University Poscurossy. As a require of this inspection, the following unsatisfactory features are noted and recommendations for their correction are given.

UNSATISPACTORY PRATUPES:

- 1. Non-demolition landfill waste including wastes not even acceptable at sanitary landfills were being deposited at the demolition landfill site.
- 2. Routine techniques of spreading and corpacting the demolitions wastes were not being practiced.

COMMENTS AND RECOMMENDATIONS:

1. A considerable arount of paint sludge in 55 gallon metal drums had been disposed of on the site. It appeared that the majority of the paint sludge had been mixed with soil and had caused one area to be very odorous and extremely damp. Neither the demolition or sanitary landfill should be accepting any quantity of paint or other sludges. It is understood that a small amount might get into the landfill undetected but, it was obvious that a good portion of the sludge could and should have been turned away. Immediate steps must be taken to stop all incoming deposite of such materials and to immediately remove such materials when they some how are dumped. (Section 89-4.010 (2) (A) of the Missouri Solid Waste Rules and Regulations lists the types of materials to be accepted at a demolition landfill. Enclosed is one copy of the Rules and Regulations.

3.600 St. Louis County
West Lake Damolition Landfill

October 20, 1977

- 2. Acceptance of non-denotion wastes has been observed in the past at the demolition landfill site. It is felt that it is a combination of an inadequate sign listing the wastes to be accepted, inadequate inspection of loads coming in and a willingness to accent such non-demolition materials when they are on site. Section 18-4,819 (2) (C) 2 requires that a list of wastes to be accepted to displayed prominently at all mite entrances. No sign was observed at either entrance for the demolition landfill. A sion listing the waste to be accented pust be erected at all entrances to the demolition landfill. A responsible supervisos should be located on site who is willing to thoroughly inspect every load that comes in and to reject all non-demolition materials. Anyone caught dumping non-demolition wastes should be forced to remove such wastes to a proper disposal facility. The combination of advising prospective dumpers of what wastes are accepted via the landfill sign along with a responsible supervisor who is knowledgable about what wastes can and cannot be accepted should result in a great reduction in non-demolition wastes being dumped at the demolition landfill.
- It was observed that the demolition materials were being dumped at the top of the working face of the landfill and for the most part simply pushed over the edge of the face. Very little compaction was being accomplished. It was understood that some bulky wastes such as large concrete blocks and tree trunks cannot be compacted but, the majority of the other demolition wastes can be spread and cormacted in layers around two feet thick on or near a 3 to 1 slope. If possible, it is recommended that the demolition wastes be dumped at the base of working face. Whether the wastes are dumped at the top or base of the working face, every effort must be made to spread and compact the demolition wastes in layers not to exceed two (2) feet as much as practical from the standpoint of the size and shape of the materials. If a load is observed containing large materials that could hinder the proper compaction of other demolition wastes. it should be dimped where it can be more easily handled instead of with the other wastes. Section 80-4.010 (12) (C) I requires that solid waste handling equipment shall be capable of :
 - 1. Spreading and compacting the solid wastes accepted in layers no more than two feet thick, when practical from size and shape of the waste material, while confining it to the smallest practical area.
 - 2. Compact the solid waste to the smallest practical volume.
 - 3. Place, spread and compact the cover material as much as practical.
- 4. An extensive salvage operation was being run at the demolition

3.600 St. Louis County West Lake Demolition Landfill Page Three

October 31, 1977

CENTER OF DIMENSION OF THE COLUMN

I landfill mainly for the collection of metallic objects. It was understood that the salvaged materials are hopefully removed from the site the same day they are collected. The 1 landfill must be commended for the extensive salvage operation but, every effort must be made to remove the salvaged That we will be material daily or to keep them neatly stored on site.

cover material had been applied and had been properly compacted any areas that have been brought up to final grade should contain final cover consisting of at least two feet of compacted soil and be properly seeded.

If you have any questions concerning the above comments and recommendations, please feel free to give us a call at our St. Louis Office. Reinspections will be made to insure that any non-demolition materials are not being accepted and the materials accepted are being properly compacted. of the land

Confirmed Abandoned or Uncontrolled Hazardous Waste Disposal Sites in Missouri

January 1, 1987

Annual Report

MISSOURI
DEPARTMENT OF NATURAL RESOURCES
Division of Environmental Quality

WESTLAKE LANDFILL

Classification: Class II, Priority 2

Site Name: Westlake Landfill

Address: Bridgeton, MO 63042. Between Old Rock Hill Road and New

Rock Hill Road east of Earth City T 46 N, R 5 E, St. Charles Quadrangle

Waste Type: Organics, inorganics, solvents, pesticides, heavy metals,

acids, bases, plating wastes and radionuclides

Quantity: Unknown

Site Description:

The site is an active landfill on the Missouri River floodplain in St. Louis County. The site has been reduced to two areas (see attached legal description).

Present Owner: William McCullough, President, Westlake Landfill, Inc.,

Bridgeton, MO 63042

Environmental Problems Related to Site:

The site is an active permitted landfill which in the past accepted unknown quantities of hazardous wastes. Excavation at the site in the past reached the same depth as the groundwater. Unknown quantities of hazardous materials have been deposited in direct contact with groundwater. There is potential for contamination of groundwater and the Missouri River which is less than one mile away, directly west of the site.

Remedial Actions at Site:

The site was surveyed prior to expansion in order to separate the demolition fill area from the area identified as containing hazardous materials.

Area of Concern Related to Site:

The average natural ground elevation is 435 to 440 feet with groundwater at a shallow depth. The alluvium underlying the river is one of the most important aquifers in the state. Consequently, if contamination is occuring from the landfill, it is threatening a vital aquifer resource.

General Geologic and Hydrologic Setting:

LOCATION: Longitude 90 26' 45"; latitude 38 46' 15", St. Charles Quadrangle.

The landfill has been in existance for more than twenty years. For most of that time period, landfilling has occurred on the Missouri River floodplain. Landfilling also has taken place in a limestone quarry

adjoining the floodplain landfill. The quarry is in the St. Louis Limestone which is present along the eastern slopes of the Missouri River floodplain.

The early portion of the landfill operation included excavation and filling below the floodplain and into the groundwater of the Missouri River aquifer. Subsequent landfill operations generally were confined to filling above the floodplain surface and also in the adjoining limestone quarry. Except where operational procedures cause outbreaks of leachate to occur in the quarry or runoff water to drain into the quarry, there was no evidence of significant amounts of groundwater from the alluvial aquifer entering the limestone. For the most part, the recharge, quite limited to begin with, would be from the bedrock adjoining the alluvium into the Missouri River aquifer rather than the aquifer recharging the surrounding bedrock.

Groundwater monitoring indicates contaminant movement into the alluvial aquifer in a generally northwesterly direction. However, such monitoring to date is inadequate to verify this indication or to adequately characterize the nature of the alluvial aquifer in the vicinity of the landfill.

The Missouri River floodplain sediments consist of 15 to 20 feet of silt loam to very silty clay having moderate to high permeability. The groundwater table occurs at depths of 15 to 20 feet below floodplain level. Fluctuations of 5 to 15 feet occur during periods of high water levels when there are prolonged wet seasons that affect the Missouri River. Local wet or dry periods cause little effect other than recharge directly through the landfill. This may be the most significant risk posed by the Westlake Landfill, the poor soil covering procedures that apparently occurred during landfill operation.

Beneath the silt loam, very silty clay surface soil of the alluvium, the Missouri River alluvial sediments are characterized by a general increase in grain size associated with increasing depth. The sand increase becomes noticeable at depths of 20 to 30 feet with the percentage of gravel beginning to occur at depths of 30 to 40 feet. These coarse sediments, plus the large and perennial recharge of the river, cause the alluvium to be one of the major and most important aquifers in the state. Consequently, if contamination is occurring from the landfill, it is threatening a vital aquifer resource.

Public Drinking Water Advisory:

There are no public water systems located in the immediate vicinity of Westlake Landfill. However, the site is less than one mile from the Missouri River, which is the water source for St. Louis County Water Company's North Plant. The intake for that plant is about eight miles downstream from Westlake Landfill. Should contamination from the site reach the Missouri River, the downstream public water system could be affected.

Private wells located near the landfill may also be susceptible to contamination.

Health Assessment:

The Westlake Landfill site has been found to be contaminated with 4000 tons of chlordane, trichloroethylene and toluene, and 7000 tons of low level uranium ore wastes.

Chlordane is a broad spectrum insecticide that has been observed to cause the following symptoms: blurred vision, confusion, ataxia, delirium, coughing, abdominal pain, nausea, vomiting, diarrhea, irritability, tremors, convulsions, anuria, and cancer in laboratory animals. It attacks the central nervous system, eyes, lungs, liver, kidneys, and skin. TCE or trichloroethylene is an animal carcinogen and is also capable of causing the following symptoms: irritation of the eyes, nose and throat; dermatitis; headache, dizziness, vertigo, tremors, nausea and vomiting, irregular heartbeat, sleepiness, fatigue, blurred vision, unconsciousness, and death. Damage occurs to the respiratory system, heart, liver, kidneys, and central nervous system. Toluene has been observed to cause irritation of the eyes, respiratory tract, and skin; dermatitis, headache, dizziness, fatigue, muscular weakness, drowsiness, lack of coordination, staggering gait, skin paresthesia, collapse and coma.

Uranium is reported to cause adverse health effects in two ways: toxic chemical effects including damage to the kidney and liver, pneumoconiosis, pronounced changes in the blood and generalized injury; and radiation effects including lung cancer, osteosarcoma, and lymphoma.

Analysis of the rates of fetal death, low birth weight, and malformations for 1972-1982 showed no rate for the area significantly higher than the state average.

A well survey and water sampling has been completed, and an exposure questionnaire is presently being administered to selected residents near the site. This investigation by the Missouri Department of Health has found there are only four wells still in use in the area that are downgradient from the site. One is used only occasionally and one is not used for potable water at all. None of the wells sampled had detectable amounts of any of the chemicals disposed of at the site. None of the residents questioned so far appeared to have any adverse health effects caused by materials disposed of at the site.

Based on available information, a health threat exists due to the toxic effects of chemicals and low level uranium wastes buried at the site, and the possibility that off-site migration of these materials might occur. While there is no evidence of past or present exposure, the potential for future exposure exists based on the possibility that off-site migration might occur. Sampling and corrective containment and diversion should continue at this site until risk to the public health can more accurately be determined.

WESTLAKE LANDFILL

Classification: Class III, Priority 14

Site Name: Westlake Landfill

Address: Bridgeton, MO 63042. Between Old Rock Hill Road and New

Rock Hill Road east of Earth City, St. Louis County

T 46 N, R 5 E, St. Charles Quadrangle

Waste Type: radionuclides

Quantity: 7000 tons of low level uranium ore wastes

Site Description:

The site is part of an active landfill on the Missouri River floodplain in St. Louis County.

Present Owner: Westlake Landfill, Inc.,

Bridgeton, MO 63042

Environmental Problems Related to Site:

The site is an active permitted landfill which in the past accepted 7000 tons of low level uranium ore wastes. Excavation at the site in the past reached the same depth as the groundwater. There is potential for contamination of groundwater and the Missouri River which is less than one mile away, directly west of the site.

Remedial Actions at Site:

The site was surveyed prior to expansion in order to separate the demolition fill area from the area identified as containing hazardous materials.

The Missouri Department of Natural Resources is the lead agency for this site.

Area of Concern Related to Site:

The average natural ground elevation is 435 to 440 feet with groundwater at a shallow depth. The alluvium underlying the river is one of the most important aquifers in the state. Consequently, if contamination is occuring from the landfill, it is threatening a vital aquifer resource.

General Geologic and Hydrologic Setting:

LOCATION: Longitude 90 26' 45"; latitude 38 46' 15", St. Charles Quadrangle.

The landfill has been in existence for more than twenty years. For most of that time period, landfilling has occurred on the Missouri River floodplain. Landfilling also has taken place in a limestone quarry adjoining the floodplain landfill. The quarry is in the St. Louis Limestone which is present along the eastern slopes of the Missouri River floodplain.

The early portion of the landfill operation included excavation and filling below the floodplain and into the groundwater of the Missouri River aquifer. Subsequent landfill operations generally were confined to filling above the floodplain surface and also in the adjoining limestone quarry. Except where operational procedures cause outbreaks of leachate to occur in the quarry or runoff water to drain into the quarry, there was no evidence of significant amounts of groundwater from the alluvial aquifer entering the limestone. For the most part, the recharge, quite limited to begin with, would be from the bedrock adjoining the alluvium into the Missouri River aquifer rather than the aquifer recharging the surrounding bedrock. Near the bedrock quarry pit, however, the potential exists for draining some alluvial water into this sump. Apparently, the pit is dewatered on a continuous basis with the water pumped to discharge in the alluvial setting. Groundwater monitoring indicates general movement of the alluvial groundwater to the west and north.

The Missouri River floodplain sediments consist of 15 to 20 feet of silt loam to very silty clay having moderate to high permeability. The groundwater table occurs at depths of 15 to 20 feet below floodplain level. Fluctuations of 5 to 15 feet occur during periods of high water levels when there are prolonged wet seasons that affect the Missouri River. Local wet or dry periods cause little effect other than recharge directly through the landfill. This may be the most significant risk posed by the Westlake Landfill, the poor soil covering procedures that apparently occurred during landfill operation.

Beneath the silt loam, very silty clay surface soil of the alluvium, the Missouri River alluvial sediments are characterized by a general increase in grain size associated with increasing depth. The sand increase becomes noticeable at depths of 20 to 30 feet with the percentage of gravel beginning to occur at depths of 30 to 40 feet. These coarse sediments, plus the large and perennial recharge of the river, cause the alluvium to be one of the major and most important aquifers in the state. Consequently, if contamination is occurring from the landfill, it is threatening a vital aquifer resource.

Public Drinking Water Advisory:

There are no public water systems located in the immediate vicinity of Westlake Landfill. However, the site is less than one mile from the Missouri River, which is the water source for St. Louis County Water Company's North Plant. The intake for that plant is about eight miles downstream from Westlake Landfill. Should contamination from the site reach the Missouri River, the downstream public water system could be affected.

Private wells located near the landfill may also be susceptible to contamination.

Health Assessment:

Uranium is reported to cause adverse health effects in two ways: toxic chemical effects including damage to the kidney and liver, pneumoconiosis, pronounced changes in the blood and generalized injury; and radiation effects including lung cancer, osteosarcoma, and lymphoma.

Analysis of the rates of fetal death, low birth weight, and malformations for 1972-1982 showed no rate for the area significantly higher than the state average.

An exposure assessment including a well survey, water sampling, and an administrative exposure questionnaire was completed for the site. This investigation by the Missouri Department of Health has found there are only four wells still in use in the area that are downgradient from the site. One is used only occasionally and one is not used for potable water at all. None of the residents questioned appeared to have any adverse health effects caused by materials disposed of at the site.

Based on available information, a health threat exists due to the effects of low level uranium wastes buried at the site, and the possibility that off-site migration of these materials might occur. While there is no evidence of past or present exposure, the potential for future exposure exists based on the possibility that off-site migration might occur. Sampling and corrective containment and diversion should continue at this site until risk to the public health can more accurately be determined.

ORIGIN OF MATERIAL AND HISTORY OF LICENSE

1942-1966

BELGIN CONGO AND DOMESTIC URANIUM ORES PROCESSED AT MALLINCKRODT, INCORPORATED, AT DESTREHAN STREET FACILITY ON NORTH SIDE OF ST. LOUIS. AGREEMENT WITH U. S., BELGIANS WANTED ORE RESIDUES (DAUGHTERS) RETURNED. MATERIAL WAS HELD BY U. S., BUT NOT CLAIMED BY BELGIAN CONGO.

JANUARY 10, 1964

AEC-OAK RIDGE OPERATIONS OFFICE PUT OUT BID PACKAGE TO SELL, AS LISTED IN BID PACKAGE, TOTAL ORE RESIDUES OF 117,050 TONS OF RAFFINATE OR BARIUM SULFATE CAKE CONTAINING APPROXIMATELY 191 TONS OF URANIUM. THE 8700 TONS OF BASO₄ (LEACHED) CONTAINING 7 TONS OF URANIUM WAS ITEMIZED AS PART OF THIS PACKAGE.

EARLY 1966

CONTINENTAL MINING AND MILLING COMPANY, CHICAGO, ILLINOIS, LICENSE NO. SMA-862 PURCHASED FROM AEC-ORO. THE ORE RESIDUES WERE STORED AT ST. LOUIS AIRPORT. ORE RESIDUES WERE MOVED TO 9200 LATTY AVENUE, NAZELWOOD, MISSOURI.

DECEPBER 29, 1966

LICENSE NO. SHC-907 WAS ISSUED TO COMMERCIAL DISCOUNT CORPORATION, CHICAGO, ILLINOIS ALLOWING FOR POSSESSION OF RESIDUES, REMOVAL OF MOISTURE, AND SHIPMENT TO COTTER CORPORATION IN CANON CITY, COLORADO.

J' 1RY 1967

CONTINENTAL MINING AND MILLING TERMINATED BUSINESS, COMMERCIAL DISCOUNT CORPORATION OF CHICAGO, ILLINOIS, TOOK PHYSICAL POSSESSION OF THE FACILITIES AND SOURCE MATERIAL STOCKPILE.

DECE1/BER 31, 1969	COTTER CORPORATION, CANON CITY, COLORADO, LICENSE NO. SUB-1022 PURCHASED REMAINING
	SOURCE MATERIAL AT LATTY AVENUE.
AUGUST TO	COTTER TRANSPORTED FROM THE LATTY AVENUE SITE 10,763,41 TONS OF RESIDUE BY RAIL TO

AUGUST TO

COTTER TRANSPORTED FROM THE LATTY AVENUE SITE 10,763,41 TONS OF RESIDUE BY RAIL TO CANON

OCTOBER 1973

CITY, COLORADO. 48,544,70 TONS OF RESIDUE AND SOIL CONTAINING APPROXIMATELY SEVEN

TONS OF NATURAL URANIUM WERE TRANSPORTED TO THE WEST LAKE LANDFILL SITE.

APRIL 10, 23, AND REGION III INSPECTION AT HAZELWOOD, MISSOURI SITE AND CANON CITY, COLORADO OFFICE.

24, 1974

1'AY 10, 1974 LICENSEE SUBMITS FINAL SURVEY OF LATTY AVENUE SITE TO AEC LICENSING.

NOVEMBER 1, 1974 FINDINGS OF APRIL, 1974 INSPECTION BY REGION III ARE SENT BY LETTER FROM AEC HEADQUARTERS
TO COTTER CORPORATION ADVISING THAT DILUTION AND DISPOSAL OF ORE RESIDUES ARE NOT IN
KEEPING WITH INTENT OF PART 20. NO ITEMS OF NONCOMPLIANCE.

NOVEYBER 13, 1974 AEC LICENSING TERMINATED LICENSE NO. SUB-1002.

INSPECTION HISTORY

DATES	LICENSEE	EINDINGS
MAY 16, 17, AND AUGUST 4, 1965	CONTINENTAL MINING & MILLING COMPANY LICENSE NO. SMA-862	5 ITEMS OF NONCOMPLAINCE RE: INADEQUATE POSTING, INADEQUATE SURVEYS & PERMISSIBLE LEVEL OF RADIATION IN UNRESTRICTED AREAS
JANUARY 11, 1967	COMMERCIAL DISCOUNT CORPORATION LICENSE NO. SMC-907	2 ITEMS OF NONCOMPLIANCE RE: PERMISSIBLE LEVELS OF RADIATION IN UNRESTRICTED AREAS AND INADEQUATE POSTING
MARCH 27 AND APRIL 1, 1968	COMMERCIAL DISCOUNT CORPORATION LICENSE NO. SMC-907	2 ITEMS OF NONCOMPLIANCE RE: PERMISSIBLE LEVELS OF RADIATION IN UNRESTRICTED AREAS AND INADEQUATE SURVEYS
NOVE: BER 17, 1979	COTTER CORPORATION LICENSE NO. SUB-1022	ONE ITEM OF NONCOMPLIANCE RE: INADEQUATE SURVEYS
APRIL 10, 23, & 24, 1974	COTTER CORPORATION LICENSE NO. SUB-1022	DISPOSAL OF URANIUM BY DILUTION AND BURIAL ARE NOT IN KEEPING WITH INTENT OF AEC REGULATIONS. NOT CITED AS A NONCOMPLIANCE

CONCLUSIONS OF JUNE 22-24, AUGUST 11, 1976 INVESTIGATION

- 1. THE REMAINING ORE RESIDUES AT LATTY AVENUE SITE WERE MIXED WITH SOIL TRANSPORTED TO THE WEST LAKE LANDFILL AS REPORTED BY THE LICENSEE DURING THE APRIL, 1974 INSPECTION. HOWEVER, THE RESIDUE-SOIL MIXTURE IS COVERED BY APPROXIMATELY 3 FEET OF FILL AT WEST LAKE LANDFILL INSTEAD OF 100 FEET AS REPORTED BY THE LICENSEE.
- 2. ENVIRONMENTAL SOIL SAMPLES INDICATE THE PRESENCE OF URANIUM ORE PROCESS RESIDUES REMAINING AT THE LATTY AVENUE SITE. BETA-GAMMA SURVEYS PERFORMED BY RIII PERSONNEL AT THAT SITE ON AUGUST 11, 1976 INDICATE LEVELS OF RADIATION IN CERTAIN AREAS EXCEEDING THE CRITERIA ESTABLISHED BY THE NRC FOR DECONTAMINATION OF LAND AREAS PRIOR TO RELEASE FOR UNRESTRICTED USE.
- 3. BASED ON RADIATION MEASUREMENTS OF THE MATERIAL PRESENT AT THE WEST LAKE LANDFILL AND THE LATTY AVENUE SITE NEITHER LOCATION PRESENTS AN IMMEDIATE RADIOLOGICAL HEALTH HAZARD TO THE PUBLIC.

RECOMMENDATIONS

A MORE DETAILED ENVIRONMENTAL EVALUATION OF THE LATTY AVENUE AND THE WEST -- LAKE LAND FILL SITES SHOULD BE PERFORMED.

OAK RIDGE NATIONAL LABORATORY TO PERFORM THIS EVALUATION. ANY RECOMMENDATIONS WILL BE BASED ON THE OAK RIDGE EVALUATION.

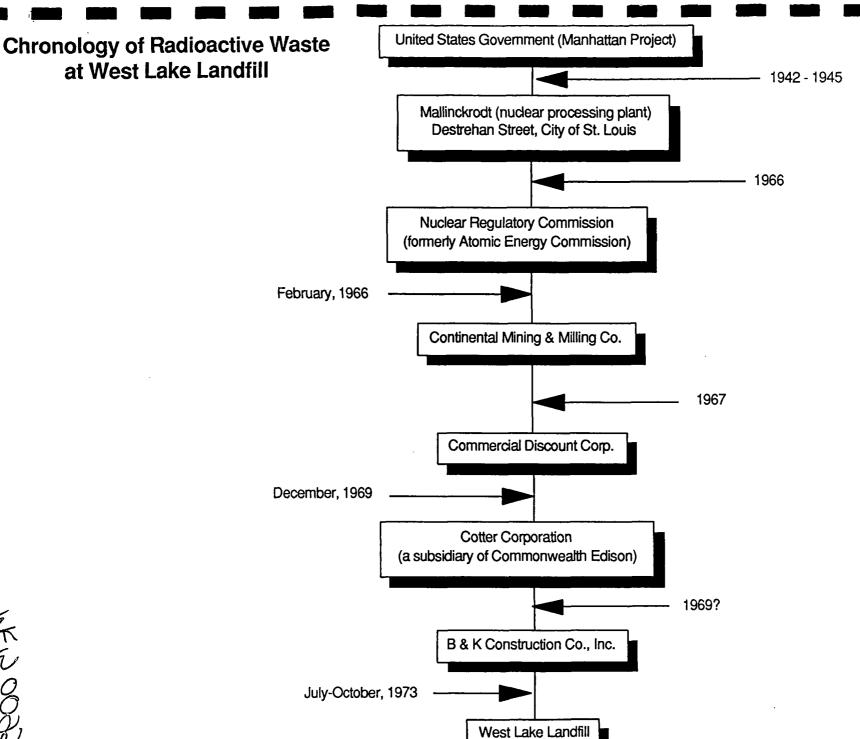

Exhibit ZZ-B
